

Calculating hypergeometric functions

August 12, 2025

1 Definitions

For $\mathbf{a} = a_1, \dots, a_p$ and $\mathbf{b} = b_1, \dots, b_q$, set $(a)_n := \Gamma(a + n)/\Gamma(a)$ and $(\mathbf{a})_n := \prod_i (a_i)_n$ and define

$${}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) := \sum_{n=0}^{\infty} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{z^n}{n!} \quad (1.1)$$

This (unregularized) function is undefined when any b_i is $0, -1, -2, \dots$, i.e. $\Gamma(\mathbf{b}) := \prod_i \Gamma(b_i)$ is infinite. When either z or $1/\Gamma(\mathbf{a})$ is zero, the series terminates and (1.1) provides a perfect definition in this case.

Since the difference in parameter counts $q+1-p$ controls the most important properties of these functions, set $d = q + 1 - p$ for any p and q . The series (1.1) defines an entire function of z for $d > 0$ and diverges for $d < 0$. For $d < 2$, the hypergeometric function can be defined in the non-terminating case on a section of the Riemann surface of $\log(-z)$ by

$${}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) = \frac{\Gamma(\mathbf{b})}{\Gamma(\mathbf{a})} \int_{-\mathrm{i}\infty}^{+\mathrm{i}\infty} \frac{\Gamma(\mathbf{a} + s)\Gamma(-s)}{\Gamma(\mathbf{b} + s)} (-z)^s \frac{ds}{2\pi\mathrm{i}}, \quad |\arg(-z)| < (2 - d)\frac{\pi}{2}. \quad (1.2)$$

When $d = 0$ the branch structure is even richer due to a singularity at $z = 1$ and the Riemann surface of \log is no longer sufficient to describe a branch. The integer d can also be viewed as a measure of the difficulty in evaluating the function: $d = 0$ can be handled by various connection formulas with convergent series, and the function poses more difficulties as d moves away from 0 due to increasingly more difficult essential singularities. The standard quantity $\sigma = \Sigma(\mathbf{b}) - \Sigma(\mathbf{a})$ is also relevant when $d \geq 0$.

Since functions accept numbers and not points on Riemann surfaces, we will use ${}_pF_q = {}_pF_q^+$ to denote the usual branch with continuity from below \mathbb{R}_+ and ${}_pF_q^-$ for the non-standard continuity from above \mathbb{R}_+ . For example, being pedantic about the branches, ${}_1F_0^-(a|z) = (-1/z)^a(1 - 1/z)^{-a}$ and ${}_2F_1(\begin{smallmatrix} a, b \\ c \end{smallmatrix} | z) = (1 - z)^{-a} {}_2F_1^-(\begin{smallmatrix} a, c-b \\ c \end{smallmatrix} | \frac{z}{z-1})$. Whenever a possibly infinite quantity $\Gamma(a_i - a_j)$ appears in a formula¹ that formula should be interpreted via a limiting case of the general formula. Also, $\hat{\mathbf{a}}_i$ denotes the length $p - 1$ vector with the i^{th} entry omitted.

The imaginary unit is denoted by $\mathrm{i} = \sqrt{-1}$, and $\mathrm{e} = 2.718\dots$

1.1 more functions

The regularized series \tilde{F} has $\Gamma(\mathbf{b} + n)$ in place of $(\mathbf{b})_n$. The bilateral series ${}_pH_q$ is defined in Section 5.4, and G denotes the standard Meijer G -function. There is a useful ${}_pU_q(z) = 1 + u_1z + \dots$ divergent series defined

¹that is, when the list \mathbf{a} has duplicates modulo \mathbb{Z}

in Section 4.1 that is essentially a Meijer G . We will also use Appell's four functions:

$$\begin{aligned} F_1(a; b_1, b_2 | x, y) &= \\ &= \\ F_2(a; b_1, b_2 | x, y) &= \\ F_3(a_1, a_2; b_1, b_2 | x, y) &= \\ F_4(a; b_1 | x, y) &= \end{aligned}$$

2 ${}_pF_q$ in the case $q + 1 = p$

Here we have several usual transcendental functions, rational possibilities, and algebraic possibilities.

$$\begin{aligned} {}_3F_2\left(\begin{matrix} 1, 2, 3 \\ 4, 5 \end{matrix} \middle| z\right) &= \frac{36}{z^3} + \frac{90}{z^2} - \frac{6}{z} + \left(\frac{36}{z^4} - \frac{36}{z^2}\right) \log(1-z) - \frac{72}{z^3} \text{Li}_2(z), \\ {}_3F_2\left(\begin{matrix} 5, 4, 3 \\ 2, 1 \end{matrix} \middle| z\right) &= \frac{140}{(1-z)^9} - \frac{315}{(1-z)^8} + \frac{240}{(1-z)^7} - \frac{70}{(1-z)^6} + \frac{6}{(1-z)^5}, \\ {}_2F_1\left(-\frac{1}{6}, \frac{1}{6}; \frac{1}{2} \middle| z\right) &= \frac{1}{2} (\sqrt{1-z} + \sqrt{-z})^{1/3} + \frac{1}{2} (\sqrt{1-z} - \sqrt{-z})^{1/3}. \end{aligned}$$

In general ${}_pF_{p-1}(z)$ has singularities at $z = 1$ and $z = \infty$ with a standard branch cut along the real axis $[1, \infty]$. For agreement with the usual transcendental functions like $\log(1-z)$, the standard value on the branch cut is determined by continuity from below.

2.1 inside unit circle

For arguments sufficiently inside the unit circle, we can just sum the series. Besides the implementation details of how to actually sum the series and bound the error, there is not much else to say here.

2.2 outside unit circle

The residues on the left of (1.2) give

$${}_pF_{p-1}\left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z\right) = \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\mathbf{b} - a_i)\Gamma(\hat{\mathbf{a}}_i)} (-z)^{-a_i} {}_pF_{p-1}^{-}\left(\begin{matrix} a_i, 1+a_i-\mathbf{b} \\ 1+a_i-\hat{\mathbf{a}}_i \end{matrix} \middle| \frac{1}{z}\right) \quad (2.1)$$

and for arguments sufficiently outside the unit circle we can just sum the series on the right.

2.3 near unit circle, away from one

The hypergeometric function can be evaluated non-rigorously near the the unit circle using various sequence transformations or Padé approximations. The series may be evaluated rigorously via a convergent series for any $z \notin [1, \infty]$ by the right hand side of

$${}_pF_{p-1}\left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z\right) = \left(\frac{1+\sqrt{1-z}}{2}\right)^{-2a_p} \sum_{n=0}^{\infty} u_n \left(\frac{1-\sqrt{1-z}}{1+\sqrt{1-z}}\right)^n \quad (2.2)$$

However, since computation of the u_n is a bit expensive, it should only be used when absolutely necessary. Furthermore, the convergence rate is only acceptable sufficiently far away from the branch cut $[1, \infty]$. The algebraic prefactor is not strictly necessary but there is good reason for it; it is present in many quadratic transformation formulas in special cases, makes the rhs terminate when the lhs does, and has the effect of lowering the order of the recurrence relation for u_n from $2p-1$ to $2p-2$.

2.3.1 ${}_2F_1(a, b; c|z)$

First of all, the u_n in (2.2) with $a_p := a$ are bounded as $u_n \ll n^{2a+2b-2c-1} + n^{2a-2b-1}$ and satisfy

$$u_0 = 1, \quad u_1 = \frac{4ab}{c} - 2a, \quad u_{n+1} = \frac{2(2b-c)(n+a)}{(n+1)(n+c)} u_n + \left(1 - \frac{2(1-2a+c)(n+a)}{(n+1)(n+c)}\right) u_{n-1}.$$

Next, Fateman cites Gosper giving $f_k \rightarrow {}_2F_1(a, b; c|z)$ (but no error bound) with

$$\begin{aligned} d_0 &= 0, & d_{k+1} &= \frac{(k+a)(k+b)z}{(k+1)(2k+c)(2k+c+1)} (e_k - (k+c-b-a) \frac{z}{1-z} d_k) \\ e_0 &= 1, & e_{k+1} &= \frac{(k+a)(k+b)z}{(k+1)(2k+c)(2k+c+1)} \left(\frac{abz}{1-z} d_k + (k+c) e_k \right) \\ f_0 &= 0, & f_{k+1} &= f_k + e_k - \frac{k((k+c-b-a)z - (2k+c)) - abz}{(2k+c)(1-z)} d_k \end{aligned}$$

Theorem 2.1. *Gosper's $f_k \rightarrow {}_2F_1(a, b; c|z)$ is correct for $\max(|\frac{z}{4}|, |\frac{z^2}{4z-4}|) < 1$.*

Remark 2.2. *Fateman also cites Gosper claiming that d_k and e_k approach zero like $|\frac{z^2}{4z-4}|^k$, but this is not correct as $\frac{z}{4}$ needs to be thrown in as well. Compare Theorem 7.20.*

Proof. Gosper's 1974 "Acceleration of Series" adapted to matrices: For sequences $A_{k,n}, B_{k,n}, S_{k,n}$ satisfying

$$\begin{aligned} \sum_{n \geq 0} A_{k,n} B_{k,n} &= \sum_{n \geq 0} A_{k,n} (B_{k,n} - S_{k,n}) + A_{k,n} S_{k,n} \\ &= A_{k,0} S_{k,0} + \sum_{n \geq 0} A_{k,n} (B_{k,n} - S_{k,n}) + A_{k,n+1} S_{k,n+1} \\ &=: A_{k,0} S_{k,0} + \sum_{n \geq 0} A_{k+1,n} B_{k+1,n}, \end{aligned}$$

iterating this last equality produces $\sum_{n \geq 0} A_{0,n} B_{0,n} = \sum_{k \geq 0} A_{k,0} S_{k,0}$. In the hypergeometric case, the $B_{k,n}$ will be simple and we would like the 'right' ratio $R_{k,n} := A_{k,n}^{-1} A_{k,n+1}$ and the 'up' ratio $U_{k,n} := A_{k,n}^{-1} A_{k+1,n}$ to be rational in n and k . As long as the following relations hold, these ratios uniquely define $A_{k,n}$ given $A_{0,0}$ and the sum identity holds.

$$\begin{aligned} R_{k,n} U_{k,n+1} &= U_{k,n} R_{k+1,n} \\ U_{k,n} B_{k+1,n} &= B_{k,n} - S_{k,n} + R_{k,n} S_{k,n+1}. \end{aligned}$$

We are looking for solutions with $R_{0,n} = \frac{(n+a)(n+b)z}{(n+1)(n+c)} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ and $B_{0,n} = \begin{pmatrix} 1 \\ n \end{pmatrix}$ since

$$\left(z \frac{\partial}{\partial z} {}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z\right) \right) = \sum_{n=0}^{\infty} \prod_{k=0}^{n-1} \frac{(k+a)(k+b)z}{(k+1)(k+c)} \cdot \begin{pmatrix} 1 \\ n \end{pmatrix}.$$

A brute force search turns up with the solution

$$\begin{aligned} R_{k,n} &= \frac{(n+k+a)(n+k+b)z}{(n+k+1)(n+2k+c)} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \\ B_{k,n} &= \begin{pmatrix} 1 \\ n+k \end{pmatrix}, \\ U_{k,n} &= \frac{(k+n+a)(k+n+b)z}{(k+n+1)(2k+n+c)(2k+n+c+1)} \left(\frac{k+c}{1-z} \frac{1}{\frac{k+c-a-b}{z-1}} \right), \\ S_{k,n} &= \left(\frac{(n+k)((k+c-a-b)z - 2k - n - c) - abz}{(2k+n+c)(z-1)} \right), \end{aligned}$$

which gives a final sum written on n ($\sum_{n=0}^{\infty} A_{n,0} S_{n,0}$) as

$$\left(z \frac{\partial}{\partial z} {}_2F_1 \left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z \right) \right) = \sum_{n=0}^{\infty} \prod_{k=0}^{n-1} \frac{(k+a)(k+b)z}{(k+1)(2k+c)(2k+c+1)} \left(\frac{k+c}{1-z} \frac{1}{z-1} \frac{(k+c-a-b)z}{z-1} \right) \cdot \left(\frac{n((n+c-b-a)z-2n-c)-abz}{(2n+c)(z-1)} \right).$$

The convergence is established by the term in the k -product being $(\frac{z}{4}, 0; 0, \frac{z^2}{4z-4}) + O(\frac{1}{k})$. This last equation also shows that starting with $d_0 = 1, e_0 = 0$ results in $f_k \rightarrow z \frac{\partial}{\partial z} {}_2F_1(a, b; c|z)$. \square

Since the $A_{0,n}$ is actually a function of the real variable n , the series acceleration formula can be differentiated with respect to n^2 , and this accelerates limiting cases of the ${}_2F_1$. With $\psi = \log \Gamma'$, define

$$\partial_k {}_2F_1 \left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z \right) := \sum_{k=0}^{\infty} \partial_k \frac{(a)_k (b)_k}{(c)_k k!} z^k = \sum_{k=0}^{\infty} \frac{(a)_k (b)_k}{(c)_k k!} z^k (\log z + \psi(a+k) + \psi(b+k) - \psi(c+k) - \psi(1+k)).$$

With $t = \log z + \psi(a) + \psi(b) - \psi(c) - \psi(1)$ and everything modulo Λ^2 , the usual way to compute this with radius of convergence $|z| < 1$ is

$${}_2F_1(z) + \partial_k {}_2F_1(z) \Lambda = (1 + t\Lambda) \sum_{n=0}^{\infty} \prod_{k=0}^{n-1} \frac{(k+a)(k+b)z}{(k+1)(2k+c)(2k+c+1)} \left(1 + \left(\frac{1}{k+a} + \frac{1}{k+b} - \frac{1}{k+c} - \frac{1}{k+1} \right) \Lambda \right),$$

and the tangent-augmented series acceleration formula is (note ∂_k and $z \frac{\partial}{\partial z}$ do commute)

$$\left(\begin{array}{c} {}_2F_1(z) + \partial_k {}_2F_1(z) \Lambda \\ z \frac{\partial}{\partial z} {}_2F_1(z) + \partial_k z \frac{\partial}{\partial z} {}_2F_1(z) \Lambda \end{array} \right) = (1 + t\Lambda) \sum_{n=0}^{\infty} \prod_{k=0}^{n-1} \frac{(k+a)(k+b)z}{(k+1)(2k+c)(2k+c+1)} \left(1 + \left(\frac{1}{k+a} + \frac{1}{k+b} - \frac{1}{k+1} - \frac{1}{2k+c} - \frac{1}{2k+c+1} \right) \Lambda \right) \cdot \left(\frac{k+c}{1-z} \frac{1}{z-1} \frac{(k+c-a-b)z}{z-1} \right) \cdot \left(\frac{n((n+c-b-a)z-2n-c)-abz}{(2n+c)(z-1)} + \left(\frac{1}{1-z} + \frac{(n+c-a)(n+c-b)z}{(2n+c)^2(z-1)} \right) \Lambda \right).$$

2.4 near one

This is the most interesting case as the function can fail to be defined at one. The existence of $F(1)$ is determined by $\Re(\sigma) > 0$. If σ is not an integer we have

$${}_pF_{p-1} \left(\begin{smallmatrix} \mathbf{a} \\ \mathbf{b} \end{smallmatrix} \middle| 1 - z \right) = \sum_{n=0}^{\infty} u_n \left(\begin{smallmatrix} \mathbf{a} \\ \mathbf{b} \end{smallmatrix} \right) z^{\sigma+n} + \sum_{n=0}^{\infty} v_n \left(\begin{smallmatrix} \mathbf{a} \\ \mathbf{b} \end{smallmatrix} \right) z^n \quad (2.3)$$

with the u_1, u_2, \dots determined from a recurrence of order $p-1$ by $u_0 = \Gamma(-\sigma)\Gamma(\mathbf{b})/\Gamma(\mathbf{a})$ and the v_{p-1}, v_p, \dots determined from a recurrence of order $p-1$ by v_0, \dots, v_{p-2} . Thus, the difficulty is computing these v_0, \dots, v_{p-2} . Gauss derived $v_0 = \Gamma(\sigma)\Gamma(b_1)/\Gamma(b_1 - \mathbf{a})$ when $p = 2$.

If σ is an integer, then at most one $\log(z)$ enters into the series.

2.4.1 ${}_2F_1$

This needs special treatment as it serves as a base case for larger p . The value of v_0 is known in this case:

$${}_2F_1 \left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| 1 \right) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} \quad \text{follows from } {}_2F_1 \left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z \right) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)} \int_0^1 t^{b-1} (1-t)^{c-b-1} (1-tz)^{-a} dt.$$

²more appropriately viewed as differentiating $\Sigma_{n \geq m} A_{k,n} B_{k,n} = \Sigma_{j \geq k} A_{j,m} S_{j,m}$ with respect to m

σ is $c - a - b$. We know from the differential equation that the u_n and v_n series in (2.3) are hypergeometric. Furthermore, as function of a, b, c , the two functions u_0 and v_0 are analytic where the three hypergeometric function are. The value at $z = 0$ determines v_0 for $\Re\sigma > 0$ which must hold everywhere by continuation. The value of u_0 similarly falls out from multiplying both sides by $z^{-\sigma}$, using $z^{a+b-c} {}_2F_1(a, b; c|1-z) = {}_2F_1(c-a, c-b; c|1-z)$, and again evaluating at $z = 0$. In total,

$${}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| 1-z\right) = \frac{\Gamma(c)\Gamma(-\sigma)}{\Gamma(a)\Gamma(b)} z^\sigma {}_2F_1\left(\begin{smallmatrix} c-a, c-b \\ 1+\sigma \end{smallmatrix} \middle| z\right) + \frac{\Gamma(c)\Gamma(\sigma)}{\Gamma(c-a)\Gamma(c-b)} {}_2F_1\left(\begin{smallmatrix} a, b \\ 1-\sigma \end{smallmatrix} \middle| z\right). \quad (2.4)$$

When $\sigma = \pm n$ is an integer, the limiting case takes the form

$${}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| 1-z\right) = \begin{cases} \frac{\Gamma(c)\Gamma(n)}{\Gamma(a)\Gamma(b)} z^{-n} \sum_{k=0}^{n-1} \frac{(c-a)_k (c-b)_k}{(1-n)_k k!} z^k - \frac{(-1)^n}{n!} \frac{\Gamma(c)}{\Gamma(c-a)\Gamma(c-b)} \partial_k {}_2F_1\left(\begin{smallmatrix} a, b \\ 1+n \end{smallmatrix} \middle| z\right), & \sigma = -n \\ \frac{\Gamma(c)\Gamma(n)}{\Gamma(c-a)\Gamma(c-b)} \sum_{k=0}^{n-1} \frac{(a)_k (b)_k}{(1-n)_k k!} z^k - \frac{(-1)^n}{n!} \frac{\Gamma(c)}{\Gamma(a)\Gamma(b)} z^n \partial_k {}_2F_1\left(\begin{smallmatrix} c-a, c-b \\ 1+n \end{smallmatrix} \middle| z\right), & \sigma = +n \end{cases}.$$

2.4.2 generic approach

We simply evaluate Equation (2.3) and its derivatives up to and including order $p-1$ at $z = 1/4$ to solve for the u_0, v_0, \dots, v_{p-2} . The explicit formula for u_0 is surprisingly useless in this approach.

2.4.3 Buehring

Here we sum the first m terms of Equation (1.1) and use a formula derived by Buehring to sum the remaining terms. Since we will be dealing with logarithmically convergent series (when $z = 1$) in both sums, it is important to balance the choice of m between the two to ensure a sub-exponential algorithm. The basic idea is that although the convergence of the series $\sum_n n^{-m}$ is ultimately slow (logarithmic), if m is large enough relative to the target precision, the “slow” part of the sum is never reached.

We have (Equations (2.7) and (2.9) in “analytic continuation of the generalized hypergeometric series near unit argument with emphasis on the zero-balanced series” by Buehring and Srivastava)

$$\begin{aligned} \sum_{n=m}^{\infty} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{z^n}{n!} &= \frac{\Gamma(\mathbf{b})}{\Gamma(\mathbf{a})} z^m \sum_{k=0}^{\infty} \frac{\Gamma(\mathbf{a}+m+k)}{\Gamma(\mathbf{b}+m+k)} \frac{z^k}{\Gamma(1+m+k)} \\ &= \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} z^m \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) {}_2F_1\left(\begin{smallmatrix} 1, a_p+m \\ 1+\sigma+a_p+m+k \end{smallmatrix} \middle| z\right) \end{aligned} \quad (2.5)$$

where the $A_k(\hat{\mathbf{a}}_p; \mathbf{b})$ are independent of m and are polynomials in $a_1, \dots, a_{p-1}, b_1, \dots, b_{p-1}$. They can be defined in the base case $p = 2$ as $A_k(a_1; b_1) = \frac{(1-a_1)_k (b_1-a_1)_k}{k!}$ and inductively for larger p by Hadamard and Cauchy products as (set $t = 1 + b_1 + \dots + b_{q-1} - a_1 - \dots - a_q$)

$$\frac{1}{(t)_k} A_k\left(\begin{smallmatrix} a_1, \dots, a_q \\ b_1, \dots, b_q \end{smallmatrix}\right) = \sum_{m+n=k} \frac{1}{(t)_m} A_m\left(\begin{smallmatrix} a_1, \dots, a_{q-1} \\ b_1, \dots, b_{q-1} \end{smallmatrix}\right) \frac{(b_q-a_q)_n}{n!}$$

The A_k satisfy an order $p-1$ recurrence and are bounded as $\frac{A_k}{k!} \ll \sum_{i < p} k^{\sigma+a_p-1-a_i}$. Convergence of the tail series is ensured by $|1 - 1/z| < 1$ and $m + \Re(a_i) > 0$ for all $i < p$ since

$$k! {}_2\tilde{F}_1\left(\begin{smallmatrix} 1, a_p+m \\ 1+\sigma+a_p+m+k \end{smallmatrix} \middle| z\right) \ll k^{-\sigma} |1 - 1/z|^k + k^{-m-\sigma-a_p}.$$

In reality the majorant method will probably produce a much worse explicit bound $|A_k/k!| \leq ck^\mu$ so we are balancing the sum of the first m terms of a sum whose terms are like $n^{-1-\sigma}$ with another series that we can only prove has terms like $k^{\mu-m-\sigma-a_p}$. Any reasonable overestimation of μ can be compensated by a larger m . Finally, in order to sum in total no more than $O(d)$ terms for d digit accuracy, it probably suffices to take $m \approx d$ for reasonable parameter ranges.

2.4.4 hybrid approach for $\sigma \notin \mathbb{Z}$

The necessary coefficients u_0 (respectively v_0, \dots, v_{p-2}) in (2.3) may be evaluated by combining (2.5) (with z replaced by $1 - z$) for $m = 0$ (respectively large m) with the expansion

$${}_2\tilde{F}_1\left(\begin{smallmatrix} 1, a_p+m \\ 1+\sigma+a_p+m+k \end{smallmatrix} \middle| 1-z\right) = \frac{\Gamma(-\sigma-k)}{\Gamma(a_p+m)} \sum_{j=0}^{\infty} \frac{(\sigma+a_p+m+k)_j}{j!} z^{\sigma+k+j} - \frac{1}{\Gamma(\sigma+a_p+m+k)} \sum_{j=0}^{\infty} \frac{(a_p+m)_j}{(-\sigma-k)_{j+1}} z^j. \quad (2.6)$$

The basic idea is that

$$\sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{(1-z)^n}{n!} \approx v_0 + v_1 z + v_2 z^2 + \dots. \quad (2.7)$$

This is no help in evaluating the u_n , but those can be found easily. We have

$$\begin{aligned} F(1-z) &= \sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{(1-z)^n}{n!} + \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} (1-z)^m \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) {}_2\tilde{F}_1\left(\begin{smallmatrix} 1, a_p+m \\ 1+\sigma+a_p+m+k \end{smallmatrix} \middle| 1-z\right) \\ &= \sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{(1-z)^n}{n!} + \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} (1-z)^m \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{\Gamma(-\sigma-k)}{\Gamma(a_p+m)} \sum_{j=0}^{\infty} \frac{(\sigma+a_p+m+k)_j}{j!} z^{\sigma+k+j} \\ &\quad + \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} (1-z)^m \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{-1}{\Gamma(\sigma+a_p+m+k)} \sum_{j=0}^{\infty} \frac{(a_p+m)_j}{(-\sigma-k)_{j+1}} z^j. \end{aligned}$$

Taking $m = 0$ and equating non-integral powers of z gives

$$\sum_{n=0}^{\infty} u_n z^{\sigma+n} = \frac{\Gamma(\mathbf{b})}{\Gamma(\hat{\mathbf{a}}_p)} \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{\Gamma(-\sigma-k)}{\Gamma(a_p)} \sum_{j=0}^{\infty} \frac{(\sigma+a_p+k)_j}{j!} z^{\sigma+k+j},$$

so that in particular $u_0 = \Gamma(-\sigma)\Gamma(\mathbf{b})/\Gamma(\mathbf{a})$ and in general

$$u_n = \frac{\Gamma(\mathbf{b})}{\Gamma(\hat{\mathbf{a}}_p)} \sum_{k+j=n} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{\Gamma(-\sigma-k)}{\Gamma(a_p)} \frac{(\sigma+a_p+k)_j}{j!}.$$

Equating integral powers of z gives

$$\sum_{n=0}^{\infty} v_n z^n = \sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{(1-z)^n}{n!} + \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} \sum_{\ell=0}^{\infty} \frac{(-m)_{\ell}}{\ell!} z^{\ell} \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{-1}{\Gamma(\sigma+a_p+m+k)} \sum_{j=0}^{\infty} \frac{(a_p+m)_j}{(-\sigma-k)_{j+1}} z^j,$$

or, for arbitrary m ,

$$\begin{aligned} v_i - [z^i] \sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{(1-z)^n}{n!} &= \sum_{\ell+j=i} \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)} \frac{(-m)_{\ell}}{\ell!} \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{-1}{\Gamma(\sigma+a_p+m+k)} \frac{(a_p+m)_j}{(-\sigma-k)_{j+1}} \\ &= \frac{\Gamma(\mathbf{b})(a_p)_m}{\Gamma(\hat{\mathbf{a}}_p)\Gamma(\sigma+a_p+m)} \sum_{j=0}^i \frac{(a_p+m)_j (-m)_{i-j}}{(i-j)!} \sum_{k=0}^{\infty} A_k\left(\begin{smallmatrix} \hat{\mathbf{a}}_p \\ \mathbf{b} \end{smallmatrix}\right) \frac{-1}{(\sigma+a_p+m)_k (-\sigma-k)_{j+1}} \end{aligned}$$

This formula for the v_i is as effective as the series in the previous section. Another formula for the v_i follows by noting that both sides of (2.3) can be differentiated, which yields

$$i!(-1)^i v_i\left(\begin{smallmatrix} \mathbf{a} \\ \mathbf{b} \end{smallmatrix}\right) = \frac{(\mathbf{a})_i}{(\mathbf{b})_i} v_0\left(\begin{smallmatrix} \mathbf{a}+i \\ \mathbf{b}+i \end{smallmatrix}\right).$$

Combining this with the above formula for v_0 gives

$$\begin{aligned} i!(-1)^i v_i(\mathbf{a}|\mathbf{b}) &= \frac{(\mathbf{a})_i}{(\mathbf{b})_i} \left(\sum_{n=0}^{m-1} \frac{(\mathbf{a}+i)_n}{(\mathbf{b}+i)_n} \frac{1}{n!} + \frac{\Gamma(\mathbf{b}+i)\Gamma(a_p+i+m)}{\Gamma(\mathbf{a}+i)\Gamma(\sigma+a_p+m)} \sum_{k=0}^{\infty} A_k(\mathbf{a}_p+i|\mathbf{b}+i) \frac{1}{(\sigma-i+k)(\sigma+a_p+m)_k} \right) \\ &= \sum_{n=0}^{m-1} \frac{(\mathbf{a})_{n+i}}{(\mathbf{b})_{n+i}} \frac{1}{n!} + \frac{\Gamma(\mathbf{b})\Gamma(a_p+i+m)}{\Gamma(\mathbf{a})\Gamma(\sigma+a_p+m)} \sum_{k=0}^{\infty} A_k(\mathbf{a}_p+i|\mathbf{b}+i) \frac{1}{(\sigma-i+k)(\sigma+a_p+m)_k}. \end{aligned}$$

Finally, replacing m by $m-i$ gives the succinct formula

$$i!(-1)^i v_i(\mathbf{a}|\mathbf{b}) = \frac{\Gamma(\mathbf{b})\Gamma(a_p+m)}{\Gamma(\mathbf{a})\Gamma(\sigma-i+a_p+m)} \sum_{k=0}^{\infty} A_k(\mathbf{a}_p+i|\mathbf{b}+i) \frac{1}{(\sigma-i+k)(\sigma-i+a_p+m)_k} + \frac{\partial^i}{\partial z^i} \Big|_{z=1} \sum_{n=0}^{m-1} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{z^n}{n!}. \quad (2.8)$$

When $\Re(\sigma) \leq i$ so that the coefficient of z^i on the left hand side of (2.7) diverges as m tends to ∞ , there is cancelation between the two sums on the right hand side of (2.8).

3 ${}_pF_q$ in the case $q+1 < p$

We shall abuse the notation and redefine $d = |d|$ in this section. This strange case includes

$$\begin{aligned} \sum_{k=0}^{\infty} k! x^k &= \int_0^{\infty} \frac{e^{-t}}{1-xt} dt, \quad x \notin (0, \infty) \\ \sum_{k=0}^{\infty} k!^2 x^{2k+2} &= \int_0^{\infty} (2e^{-t} \sin^{-1} tx)^2 dt, \quad x \in ? \\ \sum_{k=0}^{\infty} \frac{(-1)^k (2k)!}{2^{2k} k!} x^{2k+1} &= \sqrt{\pi} e^{1/x^2} \operatorname{erfc}(1/x), \quad \Re x > 0 \end{aligned}$$

The usual non-rigorous method of approximately summing these series is the “summation with optimal truncation”, that is, the sum is truncated immediately after the terms start to increase in absolute value. Whether we have a method of bounding the error or not, this method suffers from an obvious drawback: it can only deliver a limited amount of precision as the optimal truncation point is independent of the target precision. As for rigorous evaluation, the formal series is divergent except for zero argument or terminating parameters and is $1/d$ -Borel summable in a range of directions. As in “The Borel Sum of Divergent Barnes Hypergeometric Series and its Application to a Partial Differential Equation” by Kunio Ichinobe, this leads to the equality (1.2), or by the residues on the left of the integration path,

$${}_pF_q(\mathbf{a}|\mathbf{b}|z) = \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\mathbf{b} - a_i)\Gamma(\hat{\mathbf{a}}_i)} (-z)^{-a_i} {}_{q+1}F_{p-1} \left(\begin{matrix} a_i, 1+a_i-\mathbf{b} \\ 1+a_i-\hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right). \quad (3.1)$$

The series on the right are convergent. For ${}_pF_q^-$, we should take $(-1/z)^{a_i}$ in place of $(-z)^{-a_i}$.

The difficulty here is when $|z|$ is so small that the convergent series on the right hand side cannot be summed. There is also great cancelation among the terms of the right hand side for small $|z|$. In this case, a direct evaluation of the Laplace integral defining the Borel sum should be preferred. This proceeds as follows. For any “direction” ω with $\Re \omega > 0$, we have

$$k! = \int_0^{\infty} e^{-\omega t} (\omega t)^k \omega dt$$

Divide each term of (1.1) by $(dn)!$ to obtain the convergent series

$$\hat{F}(x) := \sum_{n=0}^{\infty} \frac{d^{dn}(\mathbf{a})_n}{(dn)!(\mathbf{b})_n} \frac{x^n}{n!}.$$

Then, at least formally, with $k = dn$, we have

$${}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) = \int_0^{\infty} \mathbb{e}^{-\omega t} \hat{F}(z(\omega/d)^d t^d) \omega dt.$$

The integrand has singularities at $t = d/\omega \cdot z^{-1/d} \cdot (\mathbb{e}^{2\pi i 1/d}, \dots, \mathbb{e}^{2\pi i d/d})$ and ω must be chosen so that none of these singularities lie on the path of integration, that is $z\omega^d \notin \mathbb{R}_+$.

In order to compute the usual branch of (3.1), that is, with continuity from below along the positive real axis, it suffices to take

$$\begin{aligned} \frac{\arg 1/z - 2\pi}{d} < \arg \omega < \frac{\arg 1/z}{d}, & \arg 1/z \geq 0 \\ \frac{\arg 1/z}{d} < \arg \omega < \frac{\arg 1/z + 2\pi}{d}, & \arg 1/z < 0 \end{aligned}$$

Note also that these formulas are not sensitive to the choice of argument for negative real z , that is, $\arg -1 = -\pi$ works equally as well as the usual choice $\arg -1 = \pi$.

Finally, when z ranges over a ball containing zero, a fixed direction ω cannot be determined, and we should evaluate the function by using the obvious expansion (integration by parts in the Laplace integral or a contour shift in the Melin-Barnes integral) to the optimal truncation point m

$${}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) = \sum_{n=0}^m \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \frac{z^n}{n!} + \frac{(\mathbf{a})_m}{(\mathbf{b})_m} \frac{z^m}{m!} {}_{p+1}F_{q+1} \left(\begin{matrix} \mathbf{a} + m, 1 \\ \mathbf{b} + m, 1 + m \end{matrix} \middle| z \right).$$

The Laplace integral for the second term on the right hand side needs to be bounded for some valid direction ω . For a given arbitrary z we can always choose an ω with $|\omega| = 1$, and, for example,

$$\begin{aligned} |\arg \omega| &\leq \frac{\pi}{3 + \sqrt{d-1}}, \quad \text{and} \\ |\arg -z\omega^d| &\leq \max(0, 19 - 2d) \frac{\pi}{24}. \end{aligned}$$

These conditions reduce the problem to bounding $\hat{F}(x)$ on a sector disjoint from its branch cut $[1, \infty)$. The quantity $\hat{F}(z(\omega/d)^d t^d)$ can be bounded in absolute value by the form $?t^?$ by combining (2.2) for small t and (2.1) for large t , and $\mathbb{e}^{-\omega t}$ is bounded by $\mathbb{e}^{-\Re \omega t}$.

3.1 limiting cases

In formula (4.5) below we need to deal with limiting cases of ${}_pF_q$ for $p > q + 1$, and the resummation of series containing logs introduces some minor technicalities. In this case, the formal $1/d$ -Borel transform $\mathcal{B}_{1/d} : f(z) \mapsto \hat{f}(\xi)$ is defined on monomials as

$$\mathcal{B}_{1/d} \left(z^\lambda \frac{\log(z)^j}{j!} \right) = \sum_{i=0}^j d^i \frac{\mathbf{r}\Gamma^{(i)}(d\lambda + 1)}{i!} \xi^\lambda \frac{\log(\xi)^{j-i}}{(j-i)!}, \quad \mathbf{r}\Gamma^{(i)}(s) := \frac{d^i}{ds^i} \frac{1}{\Gamma(s)}$$

and extended to formal sums via linearity. This is so defined so that the Laplace transform formally inverts the Borel transform: for any direction ω with $\Re \omega > 0$, we have the formal identity

$$f(z) = \int_0^{\infty} \mathbb{e}^{-\omega t} \hat{f}(z(\omega t)^d) \omega dt.$$

4 ${}_pF_q$ in the case $q + 1 > p$

This case has the prototypical ${}_0F_2\left(\frac{1}{3}, \frac{2}{3} \middle| z\right)$ example

$$\sum_{n=0}^{\infty} \frac{3^{3n+1} z^n}{(3n)!} = \sum_{\zeta^3=1} e^{3\zeta z^{1/3}}. \quad (4.1)$$

The series may be summed for any argument, but the problem for large $|z|$ is that many terms may be required before the partial sums start to approach the true value. The right hand side of (4.1) may be more effective due to the fact that e^z , while still being defined by ${}_0F_0(z)$, has easy argument reduction to a small box around the origin. The ratio of successive terms is

$$\frac{z}{(n+1)(n+\frac{1}{3})(n+\frac{2}{3})} \sim \frac{z}{n^3}$$

and approximately $|z|^{1/3}$ terms have to be summed before the terms start to decrease. In this case, the formal expansion

$$\begin{aligned} {}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) &\stackrel{?}{=} \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\hat{\mathbf{a}}_i)\Gamma(\mathbf{b} - a_i)} (-z)^{-a_i} {}_{q+1}F_{p-1} \left(\begin{matrix} a_i, 1 + a_i - \mathbf{b} \\ 1 + a_i - \hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right) \\ &+ \sum_{\zeta^d=1} c_{\zeta} \frac{\Gamma(\mathbf{b})}{d^{\frac{1}{2}} (2\pi)^{\frac{d-1}{2}} \Gamma(\mathbf{a})} e^{d\zeta z^{1/d}} (\zeta z^{1/d})^{\frac{d-1}{2}-\sigma} \left(1 + \frac{u_1}{d\zeta z^{1/d}} + \frac{u_2}{d^2 \zeta^2 z^{2/d}} + \cdots \right), \end{aligned} \quad (4.2)$$

which consists of $q + 1$ divergent series, might useful (recall that $p + d = q + 1$). The first p series are hypergeometric and $1/d$ -Borel summable. The last d series in $z^{-1/d}$ are 1-Borel summable, and the coefficients u_i , which are polynomials in \mathbf{a} and \mathbf{b} , satisfy recurrences of order q with $u_0 = 1$ sufficient to define the whole sequence. According to E. M. Wright in “The Asymptotic Expansion of the Generalized Hypergeometric Function”, $c_1 = 1$ and the u_i may also be defined by

$$\frac{(2\pi)^{\frac{d-1}{2}} d^{\frac{d-1}{2}-\sigma} (\mathbf{a})_n}{d^{\frac{1}{2}} d^{dn} n!} \frac{(\mathbf{a})_n}{(\mathbf{b})_n} \sim \sum_{i=0}^{\infty} \frac{u_i}{\Gamma\left(1 + dn - \frac{d-1}{2} + \sigma + i\right)}, \quad n \rightarrow \infty.$$

Since just one term ($\zeta = 1$) on the right hand side of (4.2) is the overwhelmingly dominant term of the sum in most cases, miscalculations in the summation of the divergent series can easily go unnoticed. Thus it is judicious for testing purposes to express each of the divergent series in terms of convergent series. In doing so we will give a precise definition of $1 + u_1 z + \cdots$ and a correct form of (4.2). Unfortunately, Wright’s results are only useful here when d is 1 or 2: the two asymptotically greatest terms have $c_{\zeta} = 1$, while the remaining $d - 2$ terms of smaller order have larger c_{ζ} . Thus, the non-trivial c_{ζ} are hidden behind *two* levels of overdominant expansions, and miscalculations of the c_{ζ} are even more likely to go unnoticed³.

4.1 the function ${}_pU_q$

The resummation of the divergent series $\sum_n u_n z^n$ starts with the function $\hat{U}(\xi) = \sum_{n=0}^{\infty} u_n \xi^n / n!$ with non-zero radius of convergence. Any singularity of $\hat{U}(\xi)$ stands in the way of resumming $\sum_n u_n z^n$. With $\xi \partial_{\xi}$ on the left, the differential equation for $\hat{U}(\xi)$ has the form

$$\sum_{i=0}^{q+1} (\xi \partial_{\xi})^i \Phi_i(\xi) \hat{U}(\xi) = 0, \quad \text{where} \quad \xi \Phi_{q+1}(\xi) = (\xi - 1)^p ((\xi - 1)^d - (-1)^d).$$

³The Ma... computer algebra systems assume that $c_{\zeta} = 0$ for $\zeta \neq 1$ and $d > 2$.

Thus there are $p + d - 1$ singularities at the center or on the perimeter of the circle centered at $\xi = 1$ with a radius of 1, and we have the following lemma with θ defined as

$$\theta := \begin{cases} \frac{\pi}{2} + \frac{\pi}{d}, & d > 1 \\ \pi, & d = 1 \end{cases}.$$

Lemma 4.1. *The function $\hat{U}(\xi)$ satisfies a monic linear homogenous differential equation of order $q + 1$ with rational coefficients that are regular and bounded on the sector $|\arg(-\xi)| < \theta$. The denominator of these rational functions may be taken to be $\Phi_{q+1}(\xi)$.*

We are lucky that singularities are only present in the differential equation in $\Re \xi > 0$, so we can define a continuous sum away from \mathbb{R}_+ . On the Riemann surface of \log , this means that we can sum past $|\arg(-z)| \leq \pi$, but not by much, and by a lesser amount with larger d .

Lemma 4.2. *For a direction ω chosen so that $\Re \omega > 0$ and $|\arg(-z\omega)| < \theta$,*

$${}_pU_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) := \int_0^\infty e^{-\omega t} \hat{U}(z\omega t) \omega dt$$

defines an analytic function on $\mathbb{C} \setminus \mathbb{R}_+$ such that for any ζ with $\zeta^d = 1$ a solution of the hypergeometric differential equation is given by

$$f_\zeta(z) := e^{d\zeta z^{1/d}} (\zeta z^{1/d})^{\frac{d-1}{2}-\sigma} {}_pU_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| \frac{1}{d\zeta z^{1/d}} \right).$$

The parameter symmetries in the following lemma indicate that a more symmetric definition of the $U(z)$ series is in order. For now we keep the $(\mathbf{a}; \mathbf{b})$ of the original hypergeometric differential equation, but a notation where the following symmetry is self-evident would be more desirable.

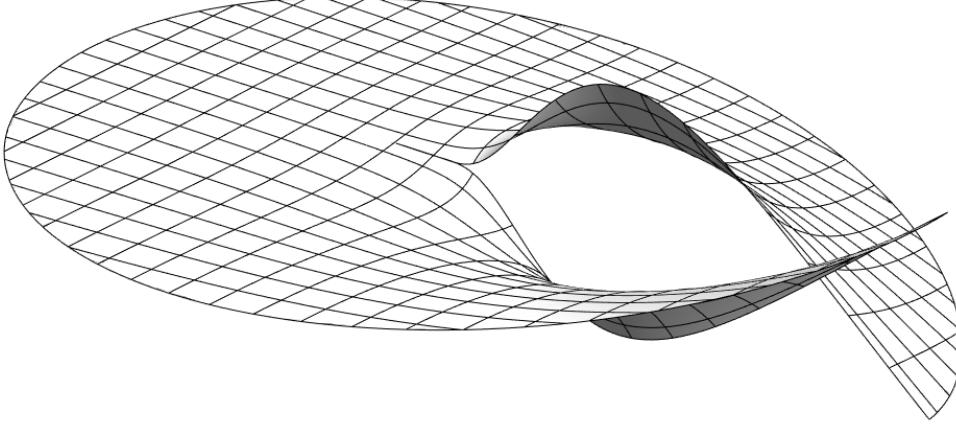

Lemma 4.3. ${}_pU_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) = {}_pU_q \left(\begin{matrix} 1 - b_i + \mathbf{a} \\ 1 - b_i + (1, \hat{\mathbf{b}}_i) \end{matrix} \middle| z \right).$

Lemma 4.4. *Set $\sigma_i = \Sigma \mathbf{b}^i - \Sigma \mathbf{a}^i$ so that $\sigma_1 = \sigma$ and $\sigma_0 = d - 1$. For any $|\arg(-z)| \leq \pi$, we have the asymptotic expansion in integral powers of z as $z \rightarrow 0$,*

$$\begin{aligned} {}_pU_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) &\sim 1 + \left(\frac{(d-1)(d-11)}{24d} + \frac{\sigma_1}{d} + \frac{\sigma_1^2}{2d} - \frac{\sigma_2}{2} \right) dz \\ &+ \left(\frac{(d-1)(d^3 - 23d^2 + 359d - 769)}{1152d^2} + \frac{(d^2 - 24d + 47)\sigma_1}{24d^2} + \frac{(d^2 - 12d + 95)\sigma_1^2}{48d^2} \right. \\ &\quad \left. - \frac{(d^2 - 12d + 47)\sigma_2}{48d} + \frac{5\sigma_1^3}{6d^2} - \frac{\sigma_1\sigma_2}{d} + \frac{\sigma_3}{6} + \frac{\sigma_1^4}{8d^2} - \frac{\sigma_1^2\sigma_2}{4d} + \frac{\sigma_2^2}{8} \right) d^2 z^2 + \dots \end{aligned}$$

Remark 4.5. *We have ${}_0U_2 \left(\frac{1}{3}, \frac{2}{3} \middle| z \right) = 1$ and the following approximation of the size of the discontinuity in ${}_0U_2 \left(\frac{1}{3}, \frac{1}{2} \middle| z \right)$, with a plot of the imaginary part of $U(z)$ shown below.*

$$\frac{{}_0U_2 \left(\frac{1}{3}, \frac{1}{2} \middle| x - \epsilon i \right) - {}_0U_2 \left(\frac{1}{3}, \frac{1}{2} \middle| x + \epsilon i \right)}{2i} \sim \begin{cases} e^{-\frac{3}{2x}} \sin \left(\frac{2\pi}{9} - \frac{\sqrt{3}}{2x} \right), & x \text{ small} \\ \frac{\sqrt{\pi}(3x)^{1/6}}{2\Gamma(\frac{1}{3})}, & x \text{ large} \end{cases}, \quad x > 0.$$

4.2 solutions for the connection coefficients c_ζ in the asymptotic formula

4.2.1 matrix derivation

The $q + 1$ functions $F_\beta(z) := z^{1-\beta} {}_pF_q((1, 1 - \beta + \mathbf{a}); 1 - \beta + (1, \mathbf{b})|z)$ are ⁴ a basis for the solutions of the hypergeometric differential equation for $\beta \in (1, \mathbf{b}) = 1, b_1, \dots, b_q$. A restatement of (3.1) gives the reciprocal algebraic solutions.

$$\begin{aligned} (-z)^{-a_i} F_{p-1}^- \left(\begin{matrix} a_i, 1 + a_i - \mathbf{b} \\ 1 + a_i - \hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right) &= \frac{((-1)^{d+1} z)^{a_i} \Gamma(1 - \mathbf{b}) \Gamma(1 + a_i - \hat{\mathbf{a}}_i)}{(-z)^{a_i} \Gamma(1 - \hat{\mathbf{a}}_i) \Gamma(1 + a_i - \mathbf{b})} F_1(z) \\ &+ \sum_{j=1}^q \frac{((-1)^{d+1} z)^{a_i+1-b_j} \Gamma(b_j - (1, \hat{\mathbf{b}}_j)) \Gamma(1 + a_i - \hat{\mathbf{a}}_i)}{(-z)^{a_i} z^{1-b_j} \Gamma(b_j - \hat{\mathbf{a}}_i) \Gamma(1 + a_i - (1, \hat{\mathbf{b}}_j))} F_{b_j}(z) \end{aligned} \quad (4.3)$$

Discontinuities on \mathbb{R} in the connection coefficients have already appeared, and we write $\pm = \frac{1}{\pi i}(\log(z) - \log(-z))$ and $\mp = -\pm = \frac{1}{\pi i}(\log(-z) - \log(z))$. For example,

$$\begin{aligned} z^b (-z)^{-b} &= e^{\pm \pi i b} \\ z^{-b} (-\sqrt{z})^{2b} &= e^{\mp 2\pi i b} \\ z^{-b} (iz^{1/4})^{4b} &= e^{2\pi i b} \end{aligned} \quad \frac{((-1)^{d+1} z)^{a_i}}{(-z)^{a_i}} = \begin{cases} e^{\pm \pi i a_i}, & d \text{ odd} \\ 1, & d \text{ even} \end{cases}$$

The connection between the p algebraic asymptotic solutions and the $F_\beta(z)$ is given in (4.3). The remaining d asymptotic solutions are the $f_\zeta(z)$ of Lemma 4.2. The continuity of these functions is shown in Figure 1 and may be summarized as

1. $f_\zeta(z)$ is discontinuous on \mathbb{R}_- for all ζ (thick black arrows).
2. $f_1(z)$ is discontinuous on \mathbb{R}_+ because $U(z)$ is (squiggly line on \mathbb{R}_+).
3. $f_{-1}(z)$ (for d even) is discontinuous on \mathbb{R}_+ because $(-z^{1/d})^{\frac{d-1}{2}-\sigma}$ is (squiggly line on \mathbb{R}_-).
4. $f_\zeta(z)$ is otherwise continuous.
5. $f_\zeta(\mathbb{R}_- + \epsilon i)$ and $f_{e^{2\pi i/d}\zeta}(\mathbb{R}_- - \epsilon i)$ can generally be identified, i.e. glued together. This fails (squiggly line on \mathbb{R}_-) only when d is odd and the two sections $\zeta z^{1/d}$ and $e^{2\pi i/d}\zeta z^{1/d}$ cross \mathbb{R}_- , thus incurring the discontinuity of $(\zeta z^{1/d})^{\frac{d-1}{2}-\sigma}$.

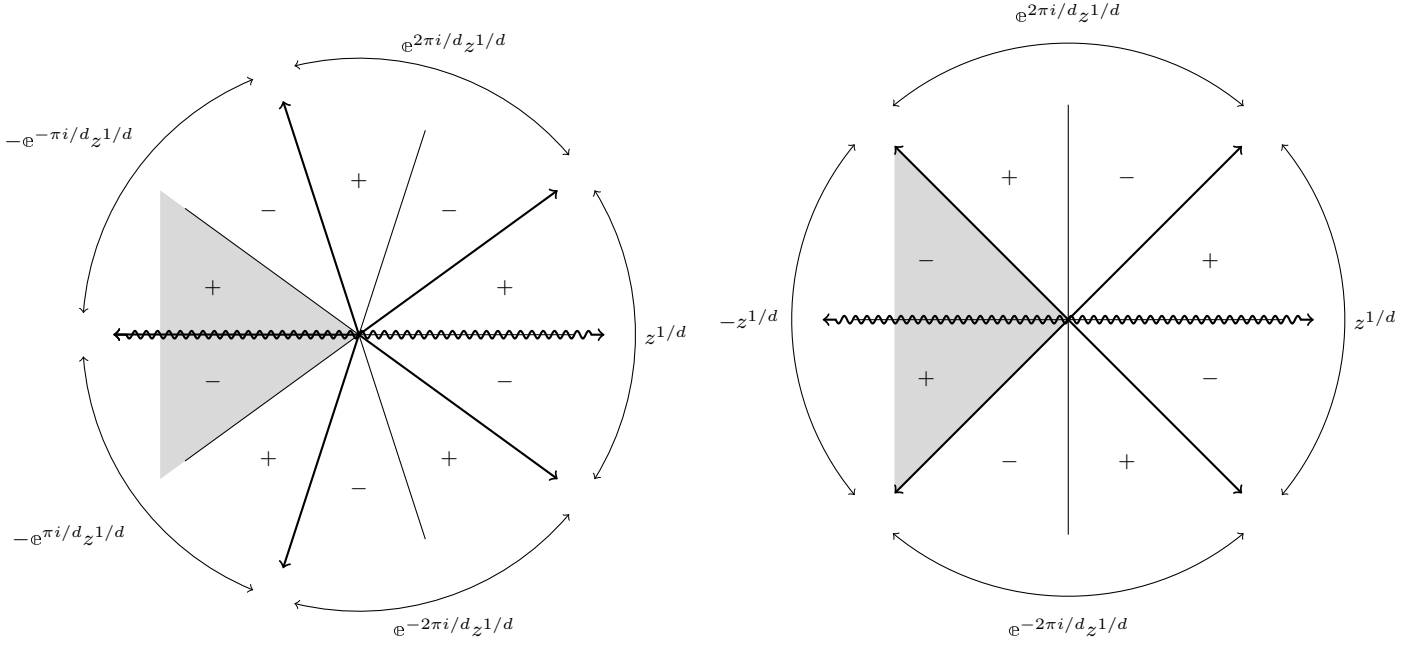

Figure 1: f_ζ glue and cuts for d odd (Left) and d even (Right)

Therefore, we will continue determining the connection coefficients on each of the two half planes $\mathbb{C}_- = \{z | \Im z < 0\}$, where $\pm = -1$, and $\mathbb{C}_+ = \{z | \Im z > 0\}$, where $\pm = +1$, and leave the determination of the connection coefficients on \mathbb{R} , which is largely a matter of convention, to the next section. For a given d^{th} root of unity ζ (and $z \in \mathbb{C} \setminus \mathbb{R}$), determine the even integer ℓ from $\pi\ell = \mp d \arg(\zeta^{\mp 1})$ and the integer k from $\pi k = \mp d \arg(-\zeta^{\mp 1})$. The f_ζ in the F_β basis are given by

$$f_\zeta(z) = \frac{e^{\pi i \operatorname{sgn}(\ell \pm 1)(\frac{d-1}{2} - \sigma)}}{d^{-\frac{1}{2}}(2\pi)^{\frac{d-1}{2}}} \left(\frac{\Gamma(1 - \mathbf{b})}{\Gamma(1 - \mathbf{a})} F_1(z) + \sum_{j=1}^q e^{k\pi i(1-b_j)} \frac{\Gamma(b_j - (1, \hat{\mathbf{b}}_j))}{\Gamma(b_j - \mathbf{a})} F_{b_j}(z) \right). \quad (4.4)$$

We will prove this first for the asymptotically smallest solution on each half plane, which corresponds to the shaded region in Figure 1. Note that since these regions straddle \mathbb{R}_- , they correspond to two different values of ζ when d is odd. We would like to show these solutions in the $F_\beta(z)$ basis are

$$\begin{aligned} f_{-1}(z) &= (4.4) \text{ with } \operatorname{sgn}(\ell \pm 1) = \mp, \text{ and } k = 0, & d \text{ even,} \\ f_{-e^{\mp \pi i/d}}(z) &= (4.4) \text{ with } \operatorname{sgn}(\ell \pm 1) = \pm, \text{ and } k = \mp, & d \text{ odd.} \end{aligned}$$

These identities follow by observing that the parenthesized sum in (4.4) is the sum of all s -residues of

$$-\frac{\Gamma(1 - s - (1, \mathbf{b}))}{\Gamma(1 - s - \mathbf{a})} z^s \times \begin{cases} 1, & d \text{ even} \\ e^{\mp \pi i s}, & d \text{ odd} \end{cases}.$$

The asymptotic value of the integral around all poles can be deduced by deforming the contour to an essentially vertical one passing through the saddle point near $s = -z^{1/d}$ and tending to $\pm i\infty$ along a path of steep descent (Lemma 4.6). The equality holds due to the uniqueness of the minimal solution.

⁴with limiting cases when the list $(1, \mathbf{b})$ has duplicates modulo \mathbb{Z}

Lemma 4.6. As $x \rightarrow \infty$ (from \mathbb{R}),

$$\int_{-\mathrm{i}\infty}^{+\mathrm{i}\infty} \frac{\Gamma(1-\mathbf{b}+s)\Gamma(s)}{\Gamma(1-\mathbf{a}+s)} x^{-ds} \frac{\mathrm{d}s}{2\pi\mathrm{i}} \sim d^{-\frac{1}{2}} (2\pi)^{\frac{d-1}{2}} \mathrm{e}^{-dx} x^{\frac{d-1}{2}-\sigma}.$$

Proof. Using $\log\Gamma(1-a+s) = s \log s - s + (\frac{1}{2} - a) \log s + \frac{1}{2} \log(2\pi) + O(s^{-1})$, the integrand is

$$\frac{\Gamma(1-\mathbf{b}+s)\Gamma(s)}{\Gamma(1-\mathbf{a}+s)} x^{-ds} = \mathrm{e}^{ds(\log s - \log x - 1) + (\frac{d-2}{2} - \sigma) \log s} \left((2\pi)^{\frac{d}{2}} + O(s^{-1}) \right)$$

With $s = x\mathrm{e}^{\mathrm{i}\theta}$ in the middle integral, the path between $\pm\mathrm{i}\infty$ can be decomposed as

$$\int_{-\mathrm{i}\infty}^{+\mathrm{i}\infty} \cdots \frac{\mathrm{d}s}{2\pi\mathrm{i}} = \int_{-\mathrm{i}\infty}^{-\mathrm{i}x} \cdots \frac{\mathrm{d}s}{2\pi\mathrm{i}} + \int_{-\frac{\pi}{2}}^{+\frac{\pi}{2}} \cdots \frac{x\mathrm{e}^{\mathrm{i}\theta} \mathrm{d}\theta}{2\pi} + \int_{+\mathrm{i}x}^{+\mathrm{i}\infty} \cdots \frac{\mathrm{d}s}{2\pi\mathrm{i}}.$$

The outer two integrals are much smaller than the claimed main term, so it is enough to focus on the integral over the half-circle.

$$\begin{aligned} \int_{-\mathrm{i}\infty}^{+\mathrm{i}\infty} \frac{\Gamma(1-\mathbf{b}+s)\Gamma(s)}{\Gamma(1-\mathbf{a})} x^{-ds} \frac{\mathrm{d}s}{2\pi\mathrm{i}} &\sim (2\pi)^{\frac{d}{2}} \int_{-\frac{\pi}{2}}^{+\frac{\pi}{2}} \mathrm{e}^{dx\mathrm{e}^{\mathrm{i}\theta}(\mathrm{i}\theta-1) + (\frac{d-2}{2}-\sigma)(\log x + \mathrm{i}\theta)} \frac{x\mathrm{e}^{\mathrm{i}\theta} \mathrm{d}\theta}{2\pi} \\ &= (2\pi)^{\frac{d-2}{2}} \mathrm{e}^{-dx} x^{\frac{d}{2}-\sigma} \int_{-\frac{\pi}{2}}^{+\frac{\pi}{2}} \mathrm{e}^{dx(\mathrm{e}^{\mathrm{i}\theta}\mathrm{i}\theta+1-\mathrm{e}^{\mathrm{i}\theta}) + (\frac{d-2}{2}-\sigma)\mathrm{i}\theta} \mathrm{d}\theta \\ (\text{set } t = \theta\sqrt{dx}) &\sim d^{-\frac{1}{2}} (2\pi)^{\frac{d-1}{2}} \mathrm{e}^{-dx} x^{\frac{d-1}{2}-\sigma} \int_{-\frac{\pi}{2}\sqrt{dx}}^{+\frac{\pi}{2}\sqrt{dx}} \frac{\mathrm{e}^{-\frac{1}{2}t^2}}{\sqrt{2\pi}} \mathrm{d}t. \end{aligned}$$

□

Now, since the $F_\beta(z)$ are either entire or have simple prefactors as z makes one trip around the origin, it is a simple matter to transform these minimal solutions back to an arbitrary $f_\zeta(z)$ by moving z around the origin a few times in either direction and using the \mathbb{C}_+ and \mathbb{C}_- gluings in point 5. This gives (4.4) and these d expansions along with the p expansions in (4.3) give a $(d+p) \times (d+p)$ matrix whose inverse has first row

$$\begin{aligned} {}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) &= \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\hat{\mathbf{a}}_i)\Gamma(\mathbf{b} - a_i)} (-z)^{-a_i} {}_{q+1}F_{p-1}^- \left(\begin{matrix} a_i, 1+a_i-\mathbf{b} \\ 1+a_i-\hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right) \\ &+ \sum_{\zeta^d=1} c^{(\pm)}(\zeta|\mathbf{a}; \mathbf{b}) \frac{\Gamma(\mathbf{b})}{d^{\frac{1}{2}}(2\pi)^{\frac{d-1}{2}}\Gamma(\mathbf{a})} \mathrm{e}^{d\zeta z^{1/d}} (\zeta z^{1/d})^{\frac{d-1}{2}-\sigma} {}_pU_q^- \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| \frac{1}{d\zeta z^{1/d}} \right), \end{aligned} \quad (4.5)$$

and this is the correct form of (4.2). The $c^{(\pm)}(\zeta)$ here are interesting combinatorial exponential sums: with the even integer ℓ determined uniquely as before from $\pi\ell = \mp d \arg(\zeta^{\mp 1})$, they are

$$c^{(\pm)}(\zeta|\mathbf{a}; \mathbf{b}) = \sum_{\substack{0 \leq n_1, \dots, n_p \\ 0 \leq m_1, \dots, m_q \leq 1 \\ \Sigma \mathbf{n} + \Sigma \mathbf{m} = (|\ell \pm 1| - 1)/2}} \mathrm{e}^{2\pi\mathrm{i} \operatorname{sgn}(\ell \pm 1)(\mathbf{n} \cdot \mathbf{a} + \mathbf{m} \cdot (\mathbf{b} + \frac{1}{2}))}. \quad (4.6)$$

The form of these exponential sums follows from, for any $p \geq 1$, $\mathbf{x} \in \mathbb{C}^p$, $\mathbf{y} \in \mathbb{C}^q$ and $0 \leq w \leq q$,

$$\begin{aligned} \sum_{\substack{0 \leq n_1, \dots, n_p \\ 0 \leq m_1, \dots, m_q \leq 1 \\ \Sigma \mathbf{n} + \Sigma \mathbf{m} = w}} \mathbf{x}^{\mathbf{n}} (-\mathbf{y})^{\mathbf{m}} &= \sum_{j=1}^p \sum_{i=0}^w \frac{x_j^{i+p-1} \Pi_{w-i}(-\mathbf{y})}{\Pi(x_j - \hat{\mathbf{x}}_j)} \\ &= \sum_{j=1}^p \sum_{i=1}^q \frac{x_j^{p-1} \Pi_w(-\hat{\mathbf{y}}_i) \Pi(x_j - \hat{\mathbf{y}}_i)}{\Pi(x_j - \hat{\mathbf{x}}_j) \Pi(y_i - \hat{\mathbf{y}}_i)}, \text{ for } w < q, \end{aligned}$$

which arise when inverting the matrix. Here, $\mathbf{x}^{\mathbf{n}} = \prod_i x_i^{n_i}$, $\Pi(\mathbf{x})$ gives the product of the x_i , and $\Pi_w(\mathbf{x})$ is the w^{th} symmetric polynomial in the x_i . See, for example, Lemma 5.1 below.

4.2.2 partial fraction derivation

Lemma 4.6 gives integral representations of the the d asymptotic solutions. For each j ranging from $1 - d$ to $d - 1$ in steps of 2, set the corresponding $\zeta = -e^{\pm\pi i \frac{j-1}{d}}$. Then, these d solutions are given by

$$\int_{-\mathbf{i}\infty}^{+\mathbf{i}\infty} \frac{\Gamma(1 - (1, \mathbf{b}) - s)}{\Gamma(1 - \mathbf{a} - s)} e^{\pm j\pi s} (-z)^s \frac{ds}{2\pi \mathbf{i}} = e^{\pm\pi \mathbf{i} \operatorname{sgn}(j-\frac{1}{2})(\frac{d-1}{2}-\sigma)} d^{-\frac{1}{2}} (2\pi)^{\frac{d-1}{2}} \times \\ e^{d\zeta z^{1/d}} (\zeta z^{1/d})^{\frac{d-1}{2}-\sigma} {}_pU_q^- \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| \frac{1}{d\zeta z^{1/d}} \right),$$

and the p algebraic asymptotic solutions are given by

$$\int_{-\mathbf{i}\infty}^{+\mathbf{i}\infty} \frac{\Gamma(1 - (1, \mathbf{b}) - s) \Gamma(a_i + s)}{\Gamma(1 - \hat{\mathbf{a}}_i - s)} ((-1)^d)^{\pm(a_i+s)} (-z)^s \frac{ds}{2\pi \mathbf{i}} = \frac{\Gamma(1 + a_i - (1, \mathbf{b}))}{\Gamma(1 + a_i - \hat{\mathbf{a}}_i)} \times \\ (-z)^{-a_i} {}_{q+1}F_{p-1}^- \left(\begin{matrix} a_i, 1 + a_i - \mathbf{b} \\ 1 + a_i - \hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right).$$

We would like to express

$$\frac{\Gamma(\mathbf{a})}{\Gamma(\mathbf{b})} {}_pF_q \left(\begin{matrix} \mathbf{a} \\ \mathbf{b} \end{matrix} \middle| z \right) = \int_{-\mathbf{i}\infty}^{+\mathbf{i}\infty} \frac{\Gamma(\mathbf{a} + s) \Gamma(-s)}{\Gamma(\mathbf{b} + s)} (-z)^s \frac{ds}{2\pi \mathbf{i}}$$

as a linear combination of the above. This is implied by

$$\frac{\Gamma(\mathbf{a} + s)}{\Gamma(\mathbf{b} + s)} = \sum_{i=1}^p h_i \frac{\Gamma(1 - \mathbf{b} - s) \Gamma(a_i + s)}{\Gamma(1 - \hat{\mathbf{a}}_i - s)} ((-1)^d)^{\pm(a_i+s)} + \sum_{\zeta^d=1} g_\zeta \frac{\Gamma(1 - \mathbf{b} - s)}{\Gamma(1 - \mathbf{a} - s)} e^{\pm j\pi s},$$

or

$$\pi^{p-q} \frac{\sin \pi(\mathbf{b} + s)}{\sin \pi(\mathbf{a} + s)} = \sum_{i=1}^p h_i \frac{((-1)^d)^{\pm(a_i+s)} \pi}{\sin \pi(a_i + s)} + \sum_{\zeta^d=1} g_\zeta e^{\pm j\pi s}.$$

Both sides are multiplied by $(-1)^{d+1}$ as $s \rightarrow s + 1$. The residue at $s = -a_i$ gives

$$h_i = \pi^{p-q-1} \frac{\sin \pi(\mathbf{b} + s)}{\sin \pi(\hat{\mathbf{a}}_i - a_i)} = \frac{\Gamma(\hat{\mathbf{a}}_i - a_i) \Gamma(1 + a_i - \hat{\mathbf{a}}_i)}{\Gamma(\hat{\mathbf{b}}_i - a_i) \Gamma(1 + a_i - \hat{\mathbf{b}}_i)}.$$

The coefficients of the remaining trigonometric polynomial can be found via power series, leading to

$$[x^k] \frac{\prod_{j=1}^q 1 - e^{+2\pi \mathbf{i} b_j} x}{\prod_{i=1}^p 1 - e^{+2\pi \mathbf{i} a_i} x} = \begin{cases} c^{(+)}(e^{+\frac{2\pi \mathbf{i}(k+0)}{d}} | \mathbf{a}, \mathbf{b}), & \text{for } k \leq \frac{d-1}{2} \\ c^{(-)}(e^{+\frac{2\pi \mathbf{i}(k+1)}{d}} | \mathbf{a}, \mathbf{b}), & \text{for } k \leq \frac{d-2}{2} \end{cases}, \\ [x^k] \frac{\prod_{j=1}^q 1 - e^{-2\pi \mathbf{i} b_j} x}{\prod_{i=1}^p 1 - e^{-2\pi \mathbf{i} a_i} x} = \begin{cases} c^{(-)}(e^{-\frac{2\pi \mathbf{i}(k+0)}{d}} | \mathbf{a}, \mathbf{b}), & \text{for } k \leq \frac{d-1}{2} \\ c^{(+)}(e^{-\frac{2\pi \mathbf{i}(k+1)}{d}} | \mathbf{a}, \mathbf{b}), & \text{for } k \leq \frac{d-2}{2} \end{cases},$$

which agrees with the previous formula (4.6).

5 The G function and bilateral series

The parameters are

- $0 \leq n \leq p$ and $0 \leq m \leq q$
- $\mathbf{a} = (\boldsymbol{\alpha}, \boldsymbol{\gamma}) \in \mathbb{C}^p$, $\boldsymbol{\alpha} = a_1, \dots, a_n$, $\boldsymbol{\gamma} = a_{n+1}, \dots, a_p$
- $\mathbf{b} = (\boldsymbol{\beta}, \boldsymbol{\delta}) \in \mathbb{C}^q$, $\boldsymbol{\beta} = b_1, \dots, b_m$, $\boldsymbol{\delta} = b_{m+1}, \dots, b_q$
- $a_i - b_j \neq 1, 2, \dots$ for any $i \leq n$ and $j \leq m$, that is, $\Gamma(1 - \boldsymbol{\alpha} + s)$ and $\Gamma(\boldsymbol{\beta} - s)$ share no poles.
- $z \in \mathbb{C}$ with $z \neq 0$

The possible paths in the definition $G_{p,q}^{m,n}(z|\boldsymbol{\alpha}, \boldsymbol{\gamma}; \boldsymbol{\beta}, \boldsymbol{\delta}) = \int \frac{\Gamma(\boldsymbol{\beta}-s)\Gamma(1-\boldsymbol{\alpha}+s)}{\Gamma(1-\boldsymbol{\delta}+s)\Gamma(\boldsymbol{\gamma}-s)} z^s \frac{ds}{2\pi i}$ are

1. from $-i\infty$ to $+i\infty$, separating the poles of $\Gamma(1 - \boldsymbol{\alpha} + s)$ from those of $\Gamma(\boldsymbol{\beta} - s)$, converges for $|\arg(z)| < (m + n - \frac{1}{2}(p + q))\pi$
2. encircle the poles of $\Gamma(\boldsymbol{\beta} - s)$ clockwise
3. encircle the poles of $\Gamma(1 - \boldsymbol{\alpha} + s)$ counterclockwise

By the shift $s \rightarrow s + 1$, the function $G((-1)^{p-m-n}z)$ is a solution to a hypergeometric differential equation:

$$(z\partial_z - b_1) \cdots (z\partial_z - b_q) - (z\partial_z - a_1) \cdots (z\partial_z - a_p)z = 0.$$

Thus it suffices to connect it to some ${}_pF_{q-1}$ ⁵.

5.1 The case $q > p$

Set $d = q - p$. Path 2 gives

$$G(z) = \sum_{j=1}^m \frac{\Gamma(\hat{\boldsymbol{\beta}}_j - b_j)\Gamma(1 + b_j - \boldsymbol{\alpha})}{\Gamma(\boldsymbol{\gamma} - b_j)\Gamma(1 + b_j - \boldsymbol{\delta})} z^{b_j} {}_pF_{q-1} \left(\begin{matrix} 1 + b_j - \mathbf{a} \\ 1 + b_j - \hat{\mathbf{b}}_j \end{matrix} \middle| (-1)^{p-m-n}z \right), \quad (5.1)$$

and this is useful if $|z|$ is not too large. We need the asymptotic expansion of $G(z)$ for large z . What is interesting here is that the poles of $\Gamma(1 - \boldsymbol{\alpha} + s)$ do not even give a hint of the correct algebraic portion; we have from (4.5),

$$\begin{aligned} G((-1)^{p-m-n}z) &= \sum_{i=1}^n \frac{h_i^{(\pm)}(\boldsymbol{\alpha}, \boldsymbol{\gamma}; \boldsymbol{\beta}, \boldsymbol{\delta})}{(2\pi i)^{p-n}} \frac{\Gamma(a_i - \hat{\mathbf{a}}_i)\Gamma(1 - a_i + \boldsymbol{\beta})}{\Gamma(a_i - \boldsymbol{\delta})} (-z)^{a_i-1} {}_qF_{p-1} \left(\begin{matrix} 1 - a_i + \mathbf{b} \\ 1 - a_i + \hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^d}{z} \right) \\ &\quad + \sum_{\zeta^d=1} \frac{g_\zeta^{(\pm)}(\boldsymbol{\alpha}, \boldsymbol{\gamma}; \boldsymbol{\beta}, \boldsymbol{\delta})}{d^{\frac{1}{2}}(2\pi)^{\frac{d-1}{2}}(2\pi i)^{1+p-m-n}} e^{d\zeta z^{1/d}} (\zeta z^{1/d})^{\Sigma \mathbf{b} - \Sigma \mathbf{a} - \frac{d-1}{2}} {}_pU_{q-1} \left(\begin{matrix} 1 + b_j - \mathbf{a} \\ 1 + b_j - \hat{\mathbf{b}}_j \end{matrix} \middle| \frac{1}{d\zeta z^{1/d}} \right), \end{aligned}$$

where the ${}_pU_{q-1}$ s on the right hand side are independent of the choice of j (Lemma 4.3), and the h_i and g_ζ are entire functions of the parameters.

$$\begin{aligned} h_i^{(\pm)} \left(\begin{matrix} \boldsymbol{\alpha}, \boldsymbol{\gamma} \\ \boldsymbol{\beta}, \boldsymbol{\delta} \end{matrix} \right) &= \sum_{j=1}^m \frac{\sin \pi(b_j - \boldsymbol{\gamma}) \sin \pi(a_i - \hat{\boldsymbol{\beta}}_j)}{\sin \pi(b_j - \hat{\boldsymbol{\beta}}_j)} (2i)^{p-n} \times \begin{cases} 1, & p - m - n \text{ odd} \\ -e^{\pm \pi i b_j}, & p - m - n \text{ even} \end{cases} \\ &= e^{-\pi i (\Sigma \boldsymbol{\gamma} + (m-1)a_i)} \times \text{some Laurent polynomial in } e^{2\pi i(\mathbf{a}, \mathbf{b})} \end{aligned}$$

⁵or limiting cases thereof

$$g_{\zeta}^{(\pm)} \left(\begin{matrix} \boldsymbol{\alpha}, \boldsymbol{\gamma} \\ \boldsymbol{\beta}, \boldsymbol{\delta} \end{matrix} \right) = \sum_{j=1}^m \frac{\sin \pi(\boldsymbol{\gamma} - b_j) c_{\zeta}^{(\pm)}(-\mathbf{a}; -\hat{\mathbf{b}}_j)}{\sin \pi(\hat{\boldsymbol{\beta}}_j - b_j)} (2i)^{1+p-m-n} \times \begin{cases} e^{-\text{pm}(\mp \zeta^{\mp}) \pi i b_j}, & p-m-n \text{ odd} \\ e^{(\text{pm}(\pm \zeta^{\mp}) \pm 1) \pi i b_j}, & p-m-n \text{ even} \end{cases} \\ = e^{-\pi i(\Sigma \boldsymbol{\gamma} + \Sigma \boldsymbol{\beta})} \times \text{some Laurent polynomial in } e^{2\pi i(\mathbf{a}, \mathbf{b})}$$

where $\text{pm}(w) := \frac{1}{\pi i}(\log(w) - \log(-w))$ so that $\pm = \text{pm}(z)$. The general form of these polynomials is too complicated to be of use: they should be generated once the parameters counts m, n, p, q are fixed. The following lemma is useful to see that the above trigonometric sums with denominator are in fact entire exponential sums.

Lemma 5.1. *Set $\mathbf{x} = x_1, \dots, x_m$ with $m \geq 1$. For any integer k ,*

$$\sum_{i=1}^m \frac{x_i^k}{\Pi(x_i - \hat{\mathbf{x}}_i)} = \begin{cases} \sum_{\substack{n_1, \dots, n_m \geq 0 \\ \Sigma \mathbf{n} = k+1-m}} \mathbf{x}^{\mathbf{n}}, & k \geq 0 \\ \sum_{\substack{n_1, \dots, n_m < 0 \\ \Sigma \mathbf{n} = k+1-m}} \mathbf{x}^{\mathbf{n}} (-1)^{m-1}, & k < 0 \end{cases}$$

Proof. Multiplying both sides by y^k and summing over all $k \geq 0$ turns the right hand side into $y^{m-1}/\Pi(1-y\mathbf{x})$ and the left and side into its partial fraction decomposition. The case $k < 0$ follows similarly. \square

5.2 The case $q < p$

Path 3 gives

$$G(z) = \sum_{i=1}^n \frac{\Gamma(a_i - \hat{\boldsymbol{\alpha}}_i) \Gamma(1 - a_i + \boldsymbol{\beta})}{\Gamma(a_i - \boldsymbol{\delta}) \Gamma(1 - a_i + \boldsymbol{\gamma})} z^{a_i-1} {}_qF_{p-1} \left(\begin{matrix} 1 - a_i + \mathbf{b} \\ 1 - a_i + \hat{\mathbf{a}}_i \end{matrix} \middle| \frac{(-1)^{q-m-n}}{z} \right), \quad (5.2)$$

and this is useful if $|z|$ is not too small. However, since $G(z|\mathbf{a}; \mathbf{b}) = G(1/z|1 - \mathbf{b}; 1 - \mathbf{a})$ modulo branch cut issues, there is no need whatsoever to consider this case.

5.3 The case $q = p$

The function is in general discontinuous on the unit circle. The expansion (5.1) is valid for $|z| < 1$, and (5.2) is valid for $|z| > 1$.

5.4 Bilateral series

The F series is a sum over Half of the integers. Accordingly, there is an H series which sums over the Full set of integers: we have ${}_pH_q(\mathbf{a}; \mathbf{b}|z)$ defined as the formal sum of $z^n(\mathbf{a})_n/(\mathbf{b})_n$ over *all* n . Specifically,

$${}_pH_q(\mathbf{a}; \mathbf{b}|z) := {}_{p+1}F_q(\mathbf{a}; \mathbf{b}^1|z) - 1 + {}_{q+1}F_p^-(\mathbf{b}^1|z) - 1 + {}_{q+1}F_p^-(\mathbf{b}^1|z),$$

with a similar definition of H^- . This gives ${}_pH_q(z)$ a branch cut along $[0, \infty]$ for $p \geq q$ and along $[0, (-1)^{p-q}\infty]$ for $p < q$, and we immediately have ${}_pH_q(\mathbf{a}; \mathbf{b}|z) = {}_qH_p^-(1 - \mathbf{b}; 1 - \mathbf{a}|(-1)^{p-q}/z)$. In terms of convergent series, (2.1) gives

$${}_pH_q(\mathbf{a}; \mathbf{b}|z) = \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(1-a_i)}{\Gamma(\hat{\mathbf{a}}_i)} \frac{\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\mathbf{b} - a_i)} (-z)^{-a_i} {}_qF_{p-1}^-(\mathbf{b}^1|z), \quad p \geq q, \\ {}_pH_q(\mathbf{a}; \mathbf{b}|(-1)^{p-q}z) = \sum_{i=1}^q \frac{\Gamma(1-\mathbf{a})\Gamma(b_i)}{\Gamma(1-\hat{\mathbf{b}}_i)} \frac{\Gamma(b_i - \hat{\mathbf{b}}_i)}{\Gamma(\mathbf{b} - a_i)} (-z)^{1-b_i} {}_pF_{q-1}(\mathbf{b}^1|z), \quad p \leq q,$$

with the special cases ${}_0H_1(b|z) = \Gamma(b)z^{1-b}e^z$,

$${}_1H_1\left(\frac{a}{b}|z\right) = \frac{\Gamma(1-a)\Gamma(b)}{\Gamma(b-a)}(-z)^{1-b}(1-z)^{b-a-1}, \quad (5.3)$$

$$\begin{aligned} {}_2H_2\left(\frac{a_1, a_2}{b_1, b_2}|z\right) &= \frac{\Gamma(1-a_1)\Gamma(1-a_2)\Gamma(b_1)\Gamma(b_1-b_2)}{\Gamma(1-b_2)\Gamma(b_1-a_1)\Gamma(b_1-a_2)}(-z)^{1-b_1}{}_2F_1\left(\frac{1+a_1-b_1, 1+a_2-b_1}{1+b_2-b_1}|z\right) \\ &+ \frac{\Gamma(1-a_1)\Gamma(1-a_2)\Gamma(b_2)\Gamma(b_2-b_1)}{\Gamma(1-b_1)\Gamma(b_2-a_1)\Gamma(b_2-a_2)}(-z)^{1-b_2}{}_2F_1\left(\frac{1+a_1-b_2, 1+a_2-b_2}{1+b_1-b_2}|z\right). \end{aligned} \quad (5.4)$$

Assuming we are on the side of the branch cut where $\log(z-1) = \pm\pi i + \log(1-z)$, this, when combined with (2.3) gives (with $\sigma := b_1 + b_2 - a_1 - a_2 - 1$)

$$\begin{aligned} {}_2H_2\left(\frac{a_1, a_2}{b_1, b_2}|1-z\right) &= \frac{\Gamma(1-a_1)\Gamma(1-a_2)\Gamma(b_1)\Gamma(b_2)\Gamma(\sigma)}{\Gamma(b_1-a_1)\Gamma(b_1-a_2)\Gamma(b_2-a_1)\Gamma(b_2-a_2)}(1+O(z)) \\ &+ \Gamma(-\sigma)z^\sigma \left(\frac{\Gamma(b_1)\Gamma(b_2)}{\Gamma(a_1)\Gamma(a_2)} + e^{\mp\pi i\sigma} \frac{\Gamma(1-b_1)\Gamma(1-b_2)}{\Gamma(1-a_1)\Gamma(1-a_2)} + O(z) \right). \end{aligned}$$

6 Appell's four functions

6.1 notes on summing general 2d D-finite series

6.2 F_1

6.3 F_2 and F_3

6.4 F_4

Fix $\sigma = c_1 + c_2 - a - b - 1$ and $\Delta = \prod 1 \pm \sqrt{x} \pm \sqrt{y}$ in this section. For the series defining $F_4(\frac{a;b}{c_1, c_2}|x, y)$, the ratio of successive terms in, for example, Theorem 7.1, has the asymptotic

$$(\sqrt{x} \pm \sqrt{y})^2(1 - (\sigma + \frac{3}{2})\frac{1}{n} + O(\frac{1}{n^2})).$$

Thus we should require $\sqrt{|x|} + \sqrt{|y|} < 1$ for absolute convergence of this power series, and we should require $\Re \sigma + \frac{1}{2} > 0$ exactly on $\Delta = 0$. This last conditions is analogous to $\Re c - a - b > 0$ being required for ${}_2F_1(a, b; c; 1)$.

6.4.1 solutions

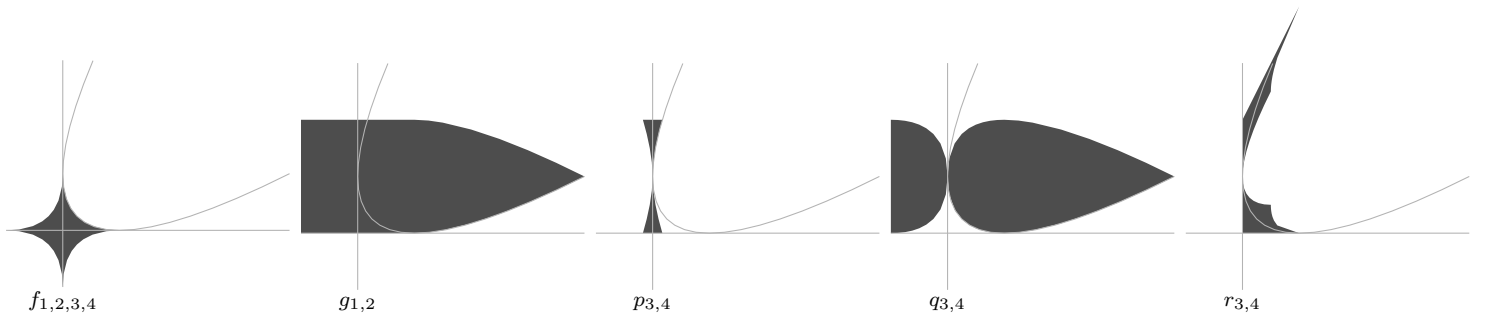

Figure 2: real convergence regions in (x, y) for the various solutions

Following H. Exton 1995 “On the system of partial differential equations associated with Appell’s function F_4 ” and Erdelyi “Integration of the Differential Equations of Appell’s F_4 ”, we will write down solutions of the F_4 equation via absolutely convergent series in each of the regions in Figure 2. Since we have, from (2.1),

$$F_4\left(\begin{smallmatrix} a;b \\ c_1,c_2 \end{smallmatrix} \middle| x, y\right) = \frac{\Gamma(c_2)\Gamma(b-a)}{\Gamma(c_2-a)\Gamma(b)}(-y)^{-a}F_4\left(\begin{smallmatrix} a;a+1-c_2 \\ c_1,a+1-b \end{smallmatrix} \middle| \frac{x}{y}, \frac{1}{y}\right) + \frac{\Gamma(c_2)\Gamma(a-b)}{\Gamma(c_2-b)\Gamma(a)}(-y)^{-b}F_4\left(\begin{smallmatrix} b;b+1-c_2 \\ c_1,b+1-a \end{smallmatrix} \middle| \frac{x}{y}, \frac{1}{y}\right),$$

the F_4 equation may be transformed to itself under $(x, y) \mapsto (x/y, 1/y)$. Along with the obvious $(x, y) \mapsto (y, x)$, this allows us to map the singular points $(0, 0)$, $(\infty, 0)$, and $(0, \infty)$ among themselves. The other set of singular points, $(0, 1)$, $(1, 0)$, and (∞, ∞) , proves to be much more difficult. Since they are also mapped to each other under these transformation is suffices to just deal with $(0, 1)$.

First, at $(0, 0)$, we have the usual power series in $(z_1, z_2) = (x, y)$ converging for $\sqrt{|z_1|} + \sqrt{|z_2|} < 1$.

$$\begin{aligned} f_1 &= F_4\left(\begin{smallmatrix} a;b \\ c_1,c_2 \end{smallmatrix} \middle| x, y\right), \\ f_2 &= x^{1-c_1}F_4\left(\begin{smallmatrix} 1+a-c_1;1+b-c_1 \\ 2-c_1,c_2 \end{smallmatrix} \middle| x, y\right), \\ f_3 &= y^{1-c_2}F_4\left(\begin{smallmatrix} 1+a-c_2;1+b-c_2 \\ c_1,2-c_2 \end{smallmatrix} \middle| x, y\right), \\ f_4 &= x^{1-c_1}y^{1-c_2}F_4\left(\begin{smallmatrix} 2+a-c_1-c_2;2+b-c_1-c_2 \\ 2-c_1,2-c_2 \end{smallmatrix} \middle| x, y\right). \end{aligned}$$

Next, as Erdelyi notes, there are only two solutions that converge in a whole neighborhood of $(0, 1)$. These are power series in $(z_1, z_2) = (x, 1 - y)$ converging for $|z_2| < 1$, $\sqrt{|z_1|} < 1 + \sqrt{1 - |z_2|}$.

$$\begin{aligned} g_1 &= \sum_{m,n=0}^{\infty} \frac{(a)_{n+m}(b)_{n+m}(1+a-c_2)_m(1+b-c_2)_m}{(1+a+b-c_2)_{n+2m}(c_1)_m} \frac{x^m(1-y)^n}{m!n!}, \\ g_2 &= x^{1-c_1}g_1\left(\begin{smallmatrix} 1+a-c_1;1+b-c_1 \\ 2-c_1,c_2 \end{smallmatrix} \middle| x, y\right). \end{aligned}$$

These g_1, g_2 can be completed to a full basis by adding two more depending on the direction of approach. There are two solutions that converge in a region approaching $(0, 1)$ along $x = 0$. These are power series in $(z_1, z_2) = (\frac{x}{(y-1)^2}, y - 1)$ converging for $|z_2| < 1$, $2\sqrt{|z_1|} + |z_1||z_2| < 1$;

$$\begin{aligned} p_3 &= (1 - y)^{c_2-a-b} \sum_{m,n=0}^{\infty} \frac{(a+b-c_2)_{2m-n}(1+a-c_2)_m(1+b-c_2)_m}{(1+a-c_2)_{m-n}(1+b-c_2)_{m-n}(c_1)_m} \frac{x^m(y-1)^{n-2m}}{m!n!}, \\ p_4 &= x^{1-c_1}p_3\left(\begin{smallmatrix} 1+a-c_1;1+b-c_1 \\ 2-c_1,c_2 \end{smallmatrix} \middle| x, y\right). \end{aligned}$$

Next, approaching $(0, 1)$ along $y = 1$ gives two more solutions as power series in $(z_1, z_2) = (\frac{(1-y)^2}{4x}, \frac{x}{4})$ converging for $\sqrt{|z_1|} + \sqrt{|z_2|} < 1$. Although it looks bad, q_3 is simply p_3 with (2.1) applied to the sum on m .

$$\begin{aligned} q_3 &= \frac{\Gamma(c_1)}{2\Gamma(a+b-c_2)}(-x)^{\frac{c_2-a-b}{2}} \sum_{n=0}^{\infty} \frac{\Gamma(\frac{a+b-n-c_2}{2})\Gamma(\frac{a-b+n-c_2+2}{2})\Gamma(\frac{-a+b+n-c_2+2}{2})}{\Gamma(\frac{a-b-n-c_2+2}{2})\Gamma(\frac{-a+b-n-c_2+2}{2})\Gamma(\frac{-a-b+n+2c_1+c_2}{2})} \frac{(-\sqrt{-x})^n}{n!} \\ &\quad {}_4F_3\left(\begin{smallmatrix} \frac{a+b-c_2-n}{2}, \frac{a+b-2c_1-c_2-n+2}{2}, \frac{a-b+c_2+n}{2}, \frac{-a+b+c_2+n}{2} \\ \frac{1}{2}, \frac{a-b+c_2-n}{2}, \frac{-a+b+c_2-n}{2} \end{smallmatrix} \middle| \frac{(1-y)^2}{4x}\right) \\ &\quad + \frac{\Gamma(\frac{a+b-n-c_2+1}{2})\Gamma(\frac{a-b+n-c_2+1}{2})\Gamma(\frac{-a+b+n-c_2+1}{2})}{\Gamma(\frac{a-b-n-c_2+1}{2})\Gamma(\frac{-a+b-n-c_2+1}{2})\Gamma(\frac{-a-b+n+2c_1+c_2-1}{2})} \frac{(1-y)(-\sqrt{-x})^{n-1}}{n!} \\ &\quad {}_4F_3\left(\begin{smallmatrix} \frac{a+b-c_2-n+1}{2}, \frac{a+b-2c_1-c_2-n+3}{2}, \frac{a-b+c_2+n+1}{2}, \frac{-a+b+c_2+n+1}{2} \\ \frac{3}{2}, \frac{a-b+c_2-n+1}{2}, \frac{-a+b+c_2-n+1}{2} \end{smallmatrix} \middle| \frac{(1-y)^2}{4x}\right), \\ q_4 &= x^{1-c_1}q_3\left(\begin{smallmatrix} 1+a-c_1;1+b-c_1 \\ 2-c_1,c_2 \end{smallmatrix} \middle| x, y\right). \end{aligned}$$

Finally, approaching $(0, 1)$ along $\Delta = 0$ gives two more solutions in $(z_1, z_2) = (\frac{\Delta}{(1-y+x)^2}, 1-y+x)$ converging for $|z_1| < 1, |z_2|(1 + \sqrt{|z_1|}) < 2$.

$$\begin{aligned} r_3 &= (1-y+x)^{1-c_1+\sigma} \sum_{m,n=0}^{\infty} \alpha_{m,n} \Delta^m (1-y+x)^{n-2m}, \\ r_4 &= \Delta^{\sigma+\frac{1}{2}} (1-y+x)^{-c_1-\sigma} \sum_{m,n=0}^{\infty} \beta_{m,n} \Delta^m (1-y+x)^{n-2m}. \end{aligned}$$

The sequences $\alpha_{m,n}$ and $\beta_{m,n}$ are not hypergeometric, but are fairly close:

$$\begin{aligned} \frac{(2m-2n-2\sigma-1)\alpha_{m,n} + (n+\sigma+c_2-1)\alpha_{m,n-1}}{2m-n-\sigma+c_1-2} &= \frac{(2m-n-\sigma+c_1-3)\alpha_{m-1,n} + (n+\sigma+c_2-1)\alpha_{m-1,n-1}}{2m} \\ \frac{2(n-m)\beta_{m,n} - (n+c_2+\sigma-1)\beta_{m,n-1}}{2m-n+c_1+\sigma-1} &= \frac{(n-2m-\sigma-c_1+2)\beta_{m-1,n} - (n+c_2+\sigma-1)\beta_{m-1,n-1}}{2m+2\sigma+1} \end{aligned}$$

Different recursions must be used along $m = 0$ and $m = n$, respectively.

Remark 6.1. An attempt should be made at simplifying r_3 and r_4 . note $\sum_{n=0}^{\infty} \beta_{0,n} z_2^n = (1 - \frac{z_2}{2})^?$.

6.4.2 connection formulas

The second equality here is (2.4) and the first provides a continuation of F_4 to the $q_{3,4}$ region.

$$F_4\left(\begin{smallmatrix} a; b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) = \frac{\Gamma(c_2)\Gamma(c_2-a-b)}{\Gamma(c_2-a)\Gamma(c_2-b)} g_1\left(\begin{smallmatrix} a, b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) + \frac{\Gamma(c_2)\Gamma(a+b-c_2)}{\Gamma(a)\Gamma(b)} q_3\left(\begin{smallmatrix} a, b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) \quad (6.1)$$

$$= \frac{\Gamma(c_2)\Gamma(c_2-a-b)}{\Gamma(c_2-a)\Gamma(c_2-b)} g_1\left(\begin{smallmatrix} a, b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) + \frac{\Gamma(c_2)\Gamma(a+b-c_2)}{\Gamma(a)\Gamma(b)} p_3\left(\begin{smallmatrix} a, b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right). \quad (6.2)$$

This is another form of (2.4):

$$g_1\left(\begin{smallmatrix} a, b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) = \frac{\Gamma(1+a+b-c_2)\Gamma(1-c_2)}{\Gamma(1+a-c_2)\Gamma(1+b-c_2)} F_4\left(\begin{smallmatrix} a; b \\ c_1, c_2 \end{smallmatrix} \middle| x, y\right) + \frac{\Gamma(1+a+b-c_2)\Gamma(c_2-1)}{\Gamma(a)\Gamma(b)} y^{1-c_2} F_4\left(\begin{smallmatrix} 1+a-c_2; 1+b-c_2 \\ c_1, 2-c_2 \end{smallmatrix} \middle| x, y\right).$$

The full change of basis matrix with the $r_{3,4}$ is

$$\begin{aligned} g_1 &= \frac{\Gamma(1+a+b-c_2)\Gamma(1-c_2)}{\Gamma(1+a-c_2)\Gamma(1+b-c_2)} f_1 + \frac{\Gamma(1+a+b-c_2)\Gamma(c_2-1)}{\Gamma(a)\Gamma(b)} f_3, \\ g_2 &= \frac{\Gamma(1+a+b-c_2)\Gamma(1-c_2)}{\Gamma(1+a-c_2)\Gamma(1+b-c_2)} f_2 + \frac{\Gamma(1+a+b-c_2)\Gamma(c_2-1)}{\Gamma(a)\Gamma(b)} f_4, \\ \frac{2^{c_1+\sigma}\Gamma(\frac{1}{2})}{\Gamma(\frac{1}{2}-\sigma)} r_3 &= \frac{\Gamma(1-c_1)\Gamma(1-c_2)\Gamma(\sigma-c_1+2)}{\Gamma(1-a)\Gamma(1-b)\Gamma(-\sigma-c_1+1)} f_1 + \frac{\Gamma(c_1-1)\Gamma(1-c_2)\Gamma(\sigma+c_1)}{\Gamma(c_1-a)\Gamma(c_1-b)\Gamma(-\sigma+c_1-1)} f_2 \\ &\quad + \frac{\Gamma(1-c_1)\Gamma(c_2-1)\Gamma(\sigma-c_1+2)}{\Gamma(c_2-a)\Gamma(c_2-b)\Gamma(-\sigma-c_1+1)} f_3 + \frac{\Gamma(c_1-1)\Gamma(c_2-1)\Gamma(\sigma+c_1)}{\Gamma(a+\sigma)\Gamma(b+\sigma)\Gamma(-\sigma+c_1-1)} f_4 \\ \frac{2^{c_1-\sigma-1}\Gamma(\frac{1}{2})}{\Gamma(\frac{3}{2}+\sigma)} r_4 &= \frac{\Gamma(1-c_1)\Gamma(1-c_2)}{\Gamma(1-a)\Gamma(1-b)} f_1 + \frac{\Gamma(c_1-1)\Gamma(1-c_2)}{\Gamma(c_1-a)\Gamma(c_1-b)} f_2 + \frac{\Gamma(1-c_1)\Gamma(c_2-1)}{\Gamma(c_2-a)\Gamma(c_2-b)} f_3 + \frac{\Gamma(c_1-1)\Gamma(c_2-1)}{\Gamma(a+\sigma)\Gamma(b+\sigma)} f_4 \end{aligned} \quad (6.3)$$

6.4.3 on $\Delta = 0$

Here the function $F_4(x, y)$ drops to rank 3 as r_4 vanishes assuming $\Re\sigma + \frac{1}{2} > 0$. The annihilator of

$$\begin{aligned} F_4\left(\begin{smallmatrix} a; b \\ c_1, c_2 \end{smallmatrix} \middle| x^2, (1-x)^2\right) &= \frac{\Gamma(c_2)\Gamma(c_2-a-b)}{\Gamma(c_2-a)\Gamma(c_2-b)} x^0 (1 + O(x)) \\ &\quad + 4^{c_1+c_2-a-b-1} \frac{\Gamma(c_1)\Gamma(c_2)\Gamma(a+b-c_2)\Gamma(c_1+c_2-a-b-\frac{1}{2})}{\Gamma(\frac{1}{2})\Gamma(a)\Gamma(b)\Gamma(2c_1+c_2-a-b-1)} x^{c_2-a-b} (1 + O(x)) \end{aligned} \quad (6.4)$$

is not difficult to compute, and the result with $\theta = x\partial_x$ on the left is

$$\begin{aligned} &\theta(\theta + 2c_1 - 2)(\theta + a + b - c_2) + (\theta + 2a - 2)(\theta + 2b - 2)(\theta + c_1 + c_2 - 3)x^2 \\ &+ (-2\theta^3 - 3(a + b + c_1 - 3)\theta^2 + (-4ab - 4ac_1 + 9a - 4bc_1 + 9b + 7c_1 - 13)\theta - 2(a - 1)(b - 1)(2c_1 - 3))x. \end{aligned}$$

The coefficient of x^{2-2c_1} in (6.4) is zero as expected (Exercise). This is equivalent to the coefficient of g_2 in the solution of (6.3) for f_1 vanishing as well.

7 Identities

7.1 notation

Much space is saved with the branch-free Bessel function $\boxed{F_a(z) := {}_0F_1(a|z)}$ so that $J_\nu(2z) = z^\nu \tilde{F}_{1+\nu}(-z^2)$. For example, Gosper's strange series

$$\sum_{n=0}^{\infty} \frac{(-1)^n J_\nu \left(\sqrt{b^2 + \pi^2(n + \frac{1}{2})^2} \right)}{n + \frac{1}{2} (b^2 + \pi^2(n + \frac{1}{2})^2)^{\nu/2}} = \frac{\pi J_\nu(b)}{2 b^\nu}$$

looks less strange in the form

$$F_a(x) = \sum_{n=0}^{\infty} \frac{(-1)^n}{\frac{\pi(2n+1)}{4}} F_a(x - (\frac{\pi(2n+1)}{4})^2)$$

7.2 polynomials

$$\frac{\frac{\partial^n}{\partial z^n} z^{a-1+n} (1-z)^{b-a+n}}{z^{a-1} (1-z)^{b-a}} = (a)_n {}_2F_1(-n, b+n | z)$$

$$\int_0^1 {}_2F_1(-m, b+m | z) {}_2F_1(-n, b+n | z) z^{a-1} (1-z)^{b-a} dz = \frac{\Gamma(a)^2 \Gamma(b-a+1+n) n!}{(b+2n) \Gamma(a+n) \Gamma(b+n)} \mathbb{1}_{m=n}$$

Theorem 7.1. *Sum with respect to total degree:*

$$\begin{aligned} F_4\left(\begin{matrix} a; b \\ c_1, c_2 \end{matrix} \middle| x, y\right) &= \sum_{n=0}^{\infty} \frac{(a)_n (b)_n x^n}{(c_1)_n n!} {}_2F_1\left(-n, 1-c_1-n \middle| \frac{y}{x}\right) \\ &= \sum_{n=0}^{\infty} \frac{(a)_n (b)_n (x-y)^n}{(c_1)_n n!} {}_2F_1\left(-n, 1+c_1+c_2+n \middle| \frac{-y}{x-y}\right). \end{aligned}$$

For integer $k \geq 0$,

$$\begin{aligned} [t^k] (1 - \tfrac{1}{t} u)^{c_1-1} {}_2F_1\left(\begin{matrix} a, b \\ c_1 \end{matrix} \middle| (1 - \tfrac{1}{t} u)(x - tv)\right) &= \frac{(a)_k (b)_k (-v)^k}{(c_1)_k k!} F_4\left(\begin{matrix} a+k; b+k \\ c_1+k, 1+k \end{matrix} \middle| x, uv\right), \\ [t^{-k}] (1 - \tfrac{1}{t} u)^{c_1-1} {}_2F_1\left(\begin{matrix} a, b \\ c_1 \end{matrix} \middle| (1 - \tfrac{1}{t} u)(x - tv)\right) &= \frac{u^k}{(1-c_1)_k k!} F_4\left(\begin{matrix} a; b \\ c_1-k, 1+k \end{matrix} \middle| x, uv\right). \end{aligned}$$

Theorem 7.2. *For $|x|, |y|$ small,*

$$\begin{aligned} \frac{(1-y)^{b-a}}{(1-x-y)^b} &= \sum_{n=0}^{\infty} \frac{(a)_n y^n}{n!} {}_2F_1\left(-n, b \middle| \frac{-x}{y}\right) \\ \frac{(1-x)^{a-b} (1-y)^{1-a}}{1-x-y} &= \sum_{n=0}^{\infty} \frac{(a)_n (y-x)^n}{n!} {}_2F_1\left(-n, b+n \middle| \frac{x(y-1)}{y-x}\right) \\ {}_2F_1\left(\begin{matrix} c, b-c \\ a \end{matrix} \middle| x\right) {}_2F_1\left(\begin{matrix} c, b-c \\ 1-a+b \end{matrix} \middle| y\right) &= \sum_{n=0}^{\infty} \frac{(b-c)_n (c)_n (y-x)^n}{(1-a+b)_n n!} {}_2F_1\left(-n, b+n \middle| \frac{x(y-1)}{y-x}\right) \\ F_a(xyz) F_{1-a+b}((1-x)(1-y)z) &= \sum_{n=0}^{\infty} \frac{(a)_n z^n {}_{F_1+b+2n}(z)}{(1-a+b)_n (b+n)_n n!} {}_2F_1\left(-n, b+n \middle| x\right) {}_2F_1\left(-n, b+n \middle| y\right) \end{aligned}$$

&= \mathcal{M}_s^{-1} \left[\frac{\Gamma(\frac{1}{2}-d+s-\frac{v}{4})\Gamma(\frac{1}{2}-d+s+\frac{v}{4})}{\Gamma(1-d-s-\frac{v}{4})\Gamma(1-d-s+\frac{v}{4})} \right] (z).
\end{aligned}$$

Theorem 7.6 (GR 7.811.1).

$$\int_0^\infty G_{p_1, q_1}^{m_1, n_1}(z_1 t | \begin{smallmatrix} \alpha_1; \gamma_1 \\ \beta_1; \delta_1 \end{smallmatrix}) G_{p_2, q_2}^{m_2, n_2}(z_2 t | \begin{smallmatrix} \alpha_2; \gamma_2 \\ \beta_2; \delta_2 \end{smallmatrix}) dt = \frac{1}{z_2} G_{p_1+q_2, q_1+p_2}^{m_1+n_2, n_1+m_2}\left(\frac{z_1}{z_2} \middle| \begin{smallmatrix} \alpha_1, -\beta_2; -\delta_2, \gamma_1 \\ \beta_1, -\alpha_2; -\gamma_2, \delta_1 \end{smallmatrix}\right)$$

Theorem 7.7.

$$\begin{aligned}
\int_0^\infty e^{-zt} F_a(ut) t^{s-1} dt &= \Gamma(s) z^{-s} {}_1F_1\left(\begin{smallmatrix} s \\ a \end{smallmatrix} \middle| \frac{u}{z}\right) \\
\int_0^\infty e^{-zt} F_a(ut) F_b(ut) t^{s-1} dt &= \Gamma(s) z^{-s} {}_3F_3\left(\begin{smallmatrix} \frac{a+b}{2}, \frac{a+b-1}{2}, s \\ a, b, a+b-1 \end{smallmatrix} \middle| \frac{4u}{z}\right) \\
\int_0^\infty e^{-zt} {}_2F_0(a, b | \frac{-1}{t}) t^{s-1} dt &= \Gamma(s) z^{-s} {}_2F_1\left(\begin{smallmatrix} a, b \\ 1-s \end{smallmatrix} \middle| z\right) + \frac{\Gamma(-s)\Gamma(a+s)\Gamma(b+s)}{\Gamma(a)\Gamma(b)} {}_2F_1\left(\begin{smallmatrix} a+s, b+s \\ 1+s \end{smallmatrix} \middle| z\right) \\
&= \frac{\Gamma(b-a)\Gamma(a+s)}{\Gamma(b)} z^{-a-s} {}_2F_1\left(\begin{smallmatrix} a, a+s \\ 1+a-b \end{smallmatrix} \middle| \frac{1}{z}\right) + \frac{\Gamma(a-b)\Gamma(b+s)}{\Gamma(a)} z^{-b-s} {}_2F_1\left(\begin{smallmatrix} b, b+s \\ 1+b-a \end{smallmatrix} \middle| \frac{1}{z}\right)
\end{aligned}$$

Theorem 7.8 (Weber-Schafheitlin discontinuous integral). *For $\alpha, \beta > 0$ and $\Re s > 0$,*

$$\int_0^\infty F_a(-\alpha t) F_b(-\beta t) t^{s-1} dt = \begin{cases} \frac{\Gamma(s)\Gamma(a)}{\alpha^s \Gamma(a-s)} {}_2F_1\left(\begin{smallmatrix} s, 1+s-a \\ b \end{smallmatrix} \middle| \frac{\beta}{\alpha}\right), & \alpha > \beta, \quad \Re 2s < \Re a + b \\ \frac{\Gamma(s)\Gamma(a)\Gamma(b)\Gamma(a+b-2s-1)}{\alpha^s \Gamma(a-s)\Gamma(b-s)\Gamma(a+b-s-1)}, & \alpha = \beta, \quad \Re 2s + 1 < \Re a + b \\ \frac{\Gamma(s)\Gamma(b)}{\beta^s \Gamma(b-s)} {}_2F_1\left(\begin{smallmatrix} s, 1+s-b \\ a \end{smallmatrix} \middle| \frac{\alpha}{\beta}\right), & \alpha < \beta, \quad \Re 2s < \Re a + b \end{cases}$$

$$\int_0^\infty F_a(-\alpha t) F_b(-\beta t) t^{a-1} dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(b-a)} \frac{((\beta-\alpha)^+)^{b-a-1}}{\beta^{b-1}}, \quad 0 < \Re a < \Re b.$$

Proof. Imitate Theorem 7.7 and let $z \rightarrow 0^+$, or use Theorem 7.6, or more boldly just integrate the series in β (resp α) to produce another absolutely convergent series. It is also not hard to argue from continuity on the boundary $\alpha = \beta$ under the additional convergence criterion. \square

Remark 7.9. *In terms of convergent series near the critical case $\alpha = \beta$, Theorem 7.8 becomes*

$$\begin{aligned} \alpha^s \int_0^\infty \tilde{F}_a(-\alpha t) \tilde{F}_b(-\beta t) t^{s-1} dt &= \frac{\Gamma(a+b-2s-1)\Gamma(s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(a+b-s-1)} {}_2F_1\left(\begin{smallmatrix} s, 1-a+s \\ 2-a-b+2s \end{smallmatrix} \middle| 1 - \frac{\beta}{\alpha}\right) \\ &+ \frac{\Gamma(1-a-b+2s)}{\pi} {}_2F_1\left(\begin{smallmatrix} b-s, a+b-s-1 \\ a+b-2s \end{smallmatrix} \middle| 1 - \frac{\beta}{\alpha}\right) \begin{cases} \sin \pi(a-s)(1 - \frac{\beta}{\alpha})^{a+b-2s-1}, & \beta < \alpha \\ \sin \pi(b-s)(\frac{\beta}{\alpha} - 1)^{a+b-2s-1}, & \beta > \alpha \end{cases}. \end{aligned}$$

Theorem 7.10. *Assume $w \log 0 < x, y < 1$ and set $\zeta = \frac{1}{2} e^{\pi i(s-\frac{1}{2}-b-c)}$:*

$$\int_0^\infty F_a(-t) F_b(-xt) F_c(-yt) t^{s-1} dt = \begin{cases} \frac{\Gamma(s)\Gamma(a)}{\Gamma(a-s)} F_4\left(\begin{smallmatrix} 1+s-a; s \\ b, c \end{smallmatrix} \middle| x, y\right), & \sqrt{x} + \sqrt{y} < 1 \\ \frac{\Gamma(s)\Gamma(a)}{\Gamma(a-s)} \left(1 + \frac{\zeta \sin \pi s}{\sin \pi b \sin \pi c}\right) F_4\left(\begin{smallmatrix} 1+s-a; s \\ b, c \end{smallmatrix} \middle| x, y\right) \\ + \frac{\zeta \Gamma(a)\Gamma(b-1)\Gamma(b)}{\sin \pi c \Gamma(b-s)\Gamma(a+b-s-1)} x^{1-b} F_4\left(\begin{smallmatrix} 1-b+s; 2-a-b+s \\ 2-b, c \end{smallmatrix} \middle| x, y\right) \\ + \frac{\zeta \Gamma(a)\Gamma(c-1)\Gamma(c)}{\sin \pi b \Gamma(c-s)\Gamma(a+c-s-1)} y^{1-c} F_4\left(\begin{smallmatrix} 1-c+s; 2-a-c+s \\ b, 2-c \end{smallmatrix} \middle| x, y\right) \\ + \frac{\zeta \Gamma(a)\Gamma(b-1)\Gamma(b)\Gamma(c-1)\Gamma(c)}{\pi \Gamma(b+c-s-1)\Gamma(a+b+c-s-2)} x^{1-b} y^{1-c} F_4\left(\begin{smallmatrix} 2-b-c+s; 3-a-b-c+s \\ 2-b, 2-c \end{smallmatrix} \middle| x, y\right) \end{cases}, \quad \sqrt{x} + \sqrt{y} > 1$$

Proof. For the first case (GR 6.578.1), ?use a 2d Theorem 7.6?, or just boldly integrate the x, y series term-by-term, being assured by the absolute convergence of the result. Bailey replaces a J_ν function with a K_ν function and then transfers back to J_ν using a limit on the imaginary axis. This gives a hint that the integral as a function of the real variables x and y satisfies the F_4 equation. However, there is no reason to suppose that the solution can be real-continued past the singular component $1 = \pm\sqrt{x} \pm \sqrt{y}$ of the differential equation. The connection coefficients on the other side can be obtained as Γ products by looking along $y = 1$ and $0 < x < 4$ using (6.1):

$$\begin{aligned} \frac{\Gamma(s)\Gamma(1+s-a)}{\Gamma(b)\Gamma(c)} F_4\left(\begin{smallmatrix} s; 1+s-a \\ b, c \end{smallmatrix} \middle| x, 1\right) &= \frac{\Gamma(s)\Gamma(1+s-a)\Gamma(a+c-2s-1)}{\Gamma(b)\Gamma(c-s)\Gamma(a+c-s-1)} {}_4F_3\left(\begin{smallmatrix} 1+s-a, s, 2+s-a-c, 1+s-c \\ b, \frac{2-a-c}{2}+s, \frac{3-a-c}{2}+s \end{smallmatrix} \middle| \frac{x}{4}\right) \\ &+ \frac{\Gamma(\frac{1-a-c}{2}+s)}{2\Gamma(\frac{a+c-1}{2}+b-s)} (-x)^{\frac{a+c-1}{2}-s} {}_4F_3\left(\begin{smallmatrix} \frac{3-a-c}{2}, \frac{1+a-c}{2}, \frac{1-a-c}{2}, \frac{a+c-1}{2} \\ \frac{1}{2}, \frac{1+a+c}{2}-s, \frac{a+c-1}{2}+b-s \end{smallmatrix} \middle| \frac{x}{4}\right) \\ &+ \frac{(a-c)(a+c-2)\Gamma(s-\frac{a+c}{2})}{8\Gamma(\frac{a+c}{2}+b-s)} (-x)^{\frac{a+c}{2}-s} {}_4F_3\left(\begin{smallmatrix} \frac{a+c}{2}, \frac{4-a-c}{2}, \frac{2+a-c}{2}, \frac{2-a+c}{2} \\ \frac{3}{2}, \frac{2+a+c}{2}-s, \frac{a+c}{2}+b-s \end{smallmatrix} \middle| \frac{x}{4}\right) \end{aligned} \quad (7.1)$$

Now, Theorem 7.18 and residues produce $\int_0^\infty F_a(-t) F_b(-xt) F_c(-t) t^{s-1} dt$ as a linear combination of the same three ${}_4F_3$ s. Doing this along $x = 1, 0 < y < 4$ as well is enough to solve for all four coefficients. \square

Remark 7.11. *Watson “a treatise on the Theory of Bessel Functions” sec 13.46 p 413 eq (7) gives a unified series that works in both cases, but this series has a horribly slow convergence rate.*

Remark 7.12. For convergent series near $\beta + \gamma = \alpha$, both cases can be combined via Section 6.4.1 into

$$\begin{aligned} \alpha^{2s} \int_0^\infty \tilde{F}_a(-\alpha^2 t) \tilde{F}_b(-\beta^2 t) \tilde{F}_c(-\gamma^2 t) t^{s-1} dt &= \frac{\Gamma(a+c-2s-1)\Gamma(s)}{\Gamma(b)\Gamma(a-s)\Gamma(c-s)\Gamma(a+c-s-1)} g_1\left(\begin{matrix} 1+s-a; s \\ b, c \end{matrix} \middle| \frac{\beta^2}{\alpha^2}, \frac{\gamma^2}{\alpha^2}\right) \\ &+ 2^{a+2b+c-2s-3} \frac{\sin \pi(a-s)\Gamma(1+2s-a-c)\Gamma(a+b+c-2s-\frac{3}{2})}{\pi^{3/2}\Gamma(a+2b+c-2s-2)} r_3\left(\begin{matrix} 1+s-a; s \\ b, c \end{matrix} \middle| \frac{\beta^2}{\alpha^2}, \frac{\gamma^2}{\alpha^2}\right) \\ &+ 2^{2s-a-c} \frac{\Gamma(\frac{3}{2}+2s-a-b-c)}{\pi^{3/2}} r_4\left(\begin{matrix} 1+s-a; s \\ b, c \end{matrix} \middle| \frac{\beta^2}{\alpha^2}, \frac{\gamma^2}{\alpha^2}\right) \begin{cases} \sin \pi(a-s), & \beta + \gamma < \alpha \\ \cos \pi(b+c-s) e^{\pi i(2s-a-b-c+\frac{1}{2})}, & \beta + \gamma > \alpha \end{cases}. \end{aligned}$$

In this form, Corollary 7.15 is immediate from the easy reduction formula

$$r_4\left(\begin{matrix} 1; a \\ a, a \end{matrix} \middle| x, y\right) = (4xy)^{1-a} (1 - 2x - 2y + x^2 - 2xy + y^2)^{a-\frac{3}{2}}.$$

Corollary 7.13 (via Theorem 7.16). Assume $wlog \alpha > \beta > \gamma > 0$ and specialize $s = \frac{a+b+c}{2} - 1$. With

$$\begin{aligned} x &= \left(\frac{\sqrt{\alpha+\beta+\gamma}\sqrt{\alpha+\beta-\gamma}-\sqrt{\alpha-\beta-\gamma}\sqrt{\alpha-\beta+\gamma}}{2\alpha}\right)^2, & y &= \left(\frac{\sqrt{\alpha+\beta+\gamma}\sqrt{\alpha+\gamma-\beta}-\sqrt{\alpha-\beta-\gamma}\sqrt{\alpha-\gamma+\beta}}{2\alpha}\right)^2, \\ 1-y &= \left(\frac{\sqrt{\alpha+\beta+\gamma}\sqrt{\alpha+\beta-\gamma}+\sqrt{\alpha-\beta-\gamma}\sqrt{\alpha-\beta+\gamma}}{2\alpha}\right)^2, & 1-x &= \left(\frac{\sqrt{\alpha+\beta+\gamma}\sqrt{\alpha+\gamma-\beta}+\sqrt{\alpha-\beta-\gamma}\sqrt{\alpha-\gamma+\beta}}{2\alpha}\right)^2, \end{aligned}$$

$$\begin{aligned} \alpha^{2s} \int_0^\infty \tilde{F}_a(-\alpha^2 t) \tilde{F}_b(-\beta^2 t) \tilde{F}_c(-\gamma^2 t) t^{\frac{a+b+c}{2}-2} dt \\ = \begin{cases} \frac{\Gamma(s)}{\Gamma(a-s)} {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ b \end{matrix} \middle| x\right) {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ c \end{matrix} \middle| y\right), & \beta + \gamma < \alpha \\ \frac{\Gamma(1+s-a)\Gamma(s)}{2\pi} \left(e^{\pi i(s+\frac{1}{2}-a)} {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ b \end{matrix} \middle| x\right) {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ c \end{matrix} \middle| y\right) \right. \\ \left. + e^{-\pi i(s+\frac{1}{2}-a)} {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ c \end{matrix} \middle| 1-x\right) {}_2\tilde{F}_1\left(\begin{matrix} 1+s-a, s \\ b \end{matrix} \middle| 1-y\right) \right), & \beta + \gamma > \alpha \end{cases} \end{aligned}$$

Corollary 7.14 (via Theorem 7.16, GR 6.578.8). Assume $\beta > \gamma > 0$ (final case is that of a possible triangle):

$$\int_0^\infty \tilde{F}_a(-\alpha^2 t) \tilde{F}_b(-\beta^2 t) \tilde{F}_c(-\gamma^2 t) t^{b-1} dt = \begin{cases} 0, & \alpha < \beta - \gamma \\ \frac{((\alpha+\beta-\gamma)(\alpha+\gamma-\beta))^{a-b-1}}{\alpha^{2a-2}\Gamma(a-b)\Gamma(b)} {}_2F_1\left(\begin{matrix} b-\frac{1}{2}, b-a+1 \\ 2b-1 \end{matrix} \middle| \frac{4\beta\gamma}{(\alpha+\beta-\gamma)(\alpha+\gamma-\beta)}\right), & \alpha > \beta + \gamma \\ \frac{((\alpha+\beta-\gamma)(\alpha+\gamma-\beta))^{a-\frac{3}{2}}}{2\alpha^{2a-2}(\beta\gamma)^{b-\frac{1}{2}}\Gamma(\frac{1}{2})\Gamma(a-\frac{1}{2})} {}_2F_1\left(\begin{matrix} b-\frac{1}{2}, \frac{3}{2}-b \\ a-\frac{1}{2} \end{matrix} \middle| \frac{(\alpha+\beta-\gamma)(\alpha+\gamma-\beta)}{4\beta\gamma}\right) \end{cases}$$

Corollary 7.15 (Sonine, GR 6.578.9). No assumptions but $\Re a > \frac{3}{2}$ (vanishes iff the triangle is impossible):

$$\int_0^\infty \tilde{F}_a(-\alpha^2 t) \tilde{F}_a(-\beta^2 t) \tilde{F}_a(-\gamma^2 t) t^{a-1} dt = \frac{((\beta+\gamma-\alpha)^+(\alpha+\gamma-\beta)^+(\alpha+\beta-\gamma)^+(\alpha+\beta+\gamma))^{a-\frac{3}{2}}}{(2\alpha\beta\gamma)^{2a-2}\Gamma(\frac{1}{2})\Gamma(a-\frac{1}{2})}.$$

7.5 Reductions

7.5.1 F_4

In some cases, a univariate specialization of the F_4 is hypergeometric. See Raimundas Vidunas “Specialization of Appell’s functions to univariate hypergeometric functions”, though correct connection coefficients are not given. There is also (7.1) for a generic $F_4(x, 1)$.

Theorem 7.16. For $|x|$ and $|y|$ small,

$$\begin{aligned} F_4\left(\begin{smallmatrix} a;b \\ c_1,c_2 \end{smallmatrix} \middle| x(1-y), y(1-x)\right) &= {}_2F_1\left(\begin{smallmatrix} a;b \\ c_1 \end{smallmatrix} \middle| x\right) {}_2F_1\left(\begin{smallmatrix} a;b \\ c_2 \end{smallmatrix} \middle| y\right), \quad \text{for } c_1 + c_2 - a - b = 1, \\ F_4\left(\begin{smallmatrix} a;b \\ b,b \end{smallmatrix} \middle| x(1-y), y(1-x)\right) &= \frac{1}{(1-x)^a(1-y)^a} {}_2F_1\left(\begin{smallmatrix} a,1+a-b \\ b \end{smallmatrix} \middle| \frac{xy}{(x-1)(y-1)}\right), \\ F_4\left(\begin{smallmatrix} a;b \\ b,b \end{smallmatrix} \middle| x^2, y^2\right) &= \frac{1}{(1-x+y)^a(1-y+x)^a} {}_2F_1\left(\begin{smallmatrix} a,b-\frac{1}{2} \\ 2b-1 \end{smallmatrix} \middle| \frac{4xy}{(1-x+y)(1-y+x)}\right), \\ F_4\left(\begin{smallmatrix} a;b \\ c_1,c_2 \end{smallmatrix} \middle| x, x\right) &= {}_4F_3\left(\begin{smallmatrix} a,b,\frac{c_1+c_2}{2},\frac{c_1+c_2-1}{2} \\ c_1,c_2,c_1+c_2-1 \end{smallmatrix} \middle| 4x\right), \\ F_4\left(\begin{smallmatrix} a;b \\ c,c \end{smallmatrix} \middle| x, -x\right) &= {}_4F_3\left(\begin{smallmatrix} \frac{a}{2},\frac{a+1}{2},\frac{b}{2},\frac{b+1}{2} \\ c,\frac{c}{2},\frac{c+1}{2} \end{smallmatrix} \middle| -4x^2\right). \end{aligned}$$

Proof. The last two follow easily from Theorem 7.1 and ${}_2F_1(\pm 1)$. □

The following records when (6.4) is a ${}_3E_2$, ${}_2E_1^{\otimes 2}$, and ${}_1E_0 \cdot {}_2E_1$ respectively.

Theorem 7.17. At least for $0 < x < 1$,

$$\begin{aligned} F_4\left(\begin{smallmatrix} a;b \\ c,\frac{1}{2} \end{smallmatrix} \middle| x^2, (1-x)^2\right) &= \frac{\Gamma(\frac{1}{2})\Gamma(\frac{1}{2}-a-b)}{\Gamma(\frac{1}{2}-a)\Gamma(\frac{1}{2}-b)} {}_3F_2\left(\begin{smallmatrix} 2a,2b,c-\frac{1}{2} \\ a+b+\frac{1}{2},2c-1 \end{smallmatrix} \middle| x\right) \\ &\quad + 2^{2c-2a-2b-1} \frac{\Gamma(c)\Gamma(c-a-b)\Gamma(a+b-\frac{1}{2})}{\Gamma(a)\Gamma(b)\Gamma(2c-a-b-\frac{1}{2})} x^{\frac{1}{2}-a-b} {}_3F_2\left(\begin{smallmatrix} \frac{1}{2}+a-b,\frac{1}{2}-a+b,c-a-b \\ \frac{3}{2}-a-b,2c-a-b-\frac{1}{2} \end{smallmatrix} \middle| x\right), \\ F_4\left(\begin{smallmatrix} 2a-\frac{1}{2};3a-1 \\ a+\frac{1}{2},a+\frac{1}{2} \end{smallmatrix} \middle| x^2, (1-x)^2\right) &= \frac{\Gamma(2-4a)\Gamma(a+\frac{1}{2})}{\Gamma(\frac{3}{2}-2a)\Gamma(1-a)} {}_2F_1\left(\begin{smallmatrix} a,3a-1 \\ 2a \end{smallmatrix} \middle| x\right)^2 \\ &\quad - 2^{-2a-2} \frac{\Gamma(2-3a)\Gamma(a-\frac{1}{2})^2\Gamma(2a)}{\pi\Gamma(1-2a)\Gamma(3a-1)} x^{2-4a} {}_2F_1\left(\begin{smallmatrix} 1-a,a \\ 2-2a \end{smallmatrix} \middle| x\right)^2, \\ F_4\left(\begin{smallmatrix} a;b \\ c,a+b-c+\frac{3}{2} \end{smallmatrix} \middle| x^2, (1-x)^2\right) &= \frac{\Gamma(\frac{3}{2}-c)\Gamma(\frac{3}{2}+a+b-c)}{\Gamma(\frac{3}{2}+a-c)\Gamma(\frac{3}{2}+b-c)} {}_2F_1\left(\begin{smallmatrix} 2a,2b \\ 2c-1 \end{smallmatrix} \middle| x\right) \\ &\quad - \frac{\Gamma(c-1)\Gamma(\frac{3}{2}+a+b-c)}{\Gamma(\frac{1}{2})\Gamma(a)\Gamma(b)} \left({}_2F_1\left(\begin{smallmatrix} 2a,2b \\ 2c-1 \end{smallmatrix} \middle| x\right) \int \frac{x^{1/2-c}}{(1-x)^{c-a-b}} {}_2F_1\left(\begin{smallmatrix} 2a-2c+2,2b-2c+2 \\ 3-2c \end{smallmatrix} \middle| x\right) dx \right. \\ &\quad \left. - x^{2-2c} {}_2F_1\left(\begin{smallmatrix} 2a-2c+2,2b-2c+2 \\ 3-2c \end{smallmatrix} \middle| x\right) \int \frac{x^{c-3/2}}{(1-x)^{c-a-b}} {}_2F_1\left(\begin{smallmatrix} 2a,2b \\ 2c-1 \end{smallmatrix} \middle| x\right) dx \right). \end{aligned}$$

7.6 Products

The product of two ${}_0F_1$ s follows easily from the ${}_2F_1(1)$ evaluation, and not from Theorem 7.20.

Theorem 7.18. $({}_2E_3 = {}_0E_1 \otimes {}_0E_1)$:

$$\begin{aligned} {}_2F_3\left(\begin{smallmatrix} \frac{a+b}{2},\frac{a+b-1}{2} \\ a,b,a+b-1 \end{smallmatrix} \middle| 4z\right) &= {}_0F_1(a|z) {}_0F_1(b|z) \\ \left(\begin{array}{c} {}_4F_1\left(\begin{smallmatrix} \frac{1}{2} \pm \frac{a}{2} \pm \frac{b}{2} \\ \frac{1}{2} \end{smallmatrix} \middle| 4z^2\right) \\ (a^2 - b^2)z {}_4F_1\left(\begin{smallmatrix} 1 \pm \frac{a}{2} \pm \frac{b}{2} \\ \frac{3}{2} \end{smallmatrix} \middle| 4z^2\right) \end{array} \right) &= \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{pmatrix} \begin{pmatrix} {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-a,\frac{1}{2}+a \\ - \end{smallmatrix} \middle| -z\right) {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-b,\frac{1}{2}+b \\ - \end{smallmatrix} \middle| z\right) \\ {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-a,\frac{1}{2}+a \\ z \end{smallmatrix}\right) {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-b,\frac{1}{2}+b \\ -z \end{smallmatrix}\right) \end{pmatrix} \\ {}_2U_3\left(\begin{smallmatrix} \frac{1+a+b}{2},\frac{2+a+b}{2} \\ 1+a,1+b,1+a+b \end{smallmatrix} \middle| z\right) &= {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-a,1\frac{1}{2}+a \\ z \end{smallmatrix}\right) {}_2F_0\left(\begin{smallmatrix} \frac{1}{2}-b,\frac{1}{2}+b \\ z \end{smallmatrix}\right) \end{aligned}$$

Of course ${}_2E_1(a,b;c|z)^2$ has no additional singularities, but it is hypergeometric only in the following case.

Theorem 7.19. $({}_3E_2 = {}_2E_1^{\otimes 2})$:

$$\begin{aligned} {}_3F_2\left(\begin{smallmatrix} 2a,2b,a+b \\ 2a+2b,\frac{1}{2}+a+b \end{smallmatrix} \middle| z\right) &= {}_2F_1\left(\begin{smallmatrix} a,b \\ \frac{1}{2}+a+b \end{smallmatrix} \middle| z\right)^2 \\ {}_3F_2\left(\begin{smallmatrix} \frac{1}{2},\frac{1}{2}+2a,\frac{1}{2}-2a \\ 1+2b,1-2b \end{smallmatrix} \middle| z\right) &= {}_2F_1\left(\begin{smallmatrix} \frac{1}{4}+a+b,\frac{1}{4}-a+b \\ 1+2b \end{smallmatrix} \middle| z\right) {}_2F_1\left(\begin{smallmatrix} \frac{1}{4}+a-b,\frac{1}{4}-a-b \\ 1-2b \end{smallmatrix} \middle| z\right) \end{aligned}$$

In general, ${}_2E_1(a, b; c|z){}_2E_1(a', b'; c'|z)$ has additional singularities at the roots of a quadratic polynomial in z with coefficients depending on a, b, c, a', b', c' . This polynomial simplifies to $2z - 1$ in the case $a' = a, b' = b, c' = 1 + a + b - c$, leading to the following quadratic transformation.

Theorem 7.20. (${}_4E_3 = {}_2E_1 \otimes {}_2E_1$):

$${}_4F_3\left(\begin{smallmatrix} a, b, \frac{a+b}{2}, \frac{1+a+b}{2} \\ a+b, 1+a+b-c, c \end{smallmatrix} \middle| 4z(1-z)\right) = {}_2F_1\left(\begin{smallmatrix} a, b \\ 1+a+b-c \end{smallmatrix} \middle| z\right){}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z\right),$$

and the ‘reciprocal’ products:

$${}_4F_3\left(\begin{smallmatrix} a, b, c-a, c-b \\ c, \frac{c}{2}, \frac{c+1}{2} \end{smallmatrix} \middle| \frac{z^2}{4(z-1)}\right) = (1-z)^a {}_2F_1\left(\begin{smallmatrix} a, c-b \\ c \end{smallmatrix} \middle| z\right){}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z\right) = {}_2F_1^-\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| \frac{z}{z-1}\right){}_2F_1\left(\begin{smallmatrix} a, b \\ c \end{smallmatrix} \middle| z\right)$$

$$\left(\begin{array}{c} \frac{1}{(1-z)^{\frac{1}{2}+a}} {}_4F_3\left(\begin{smallmatrix} \frac{1}{2}+a, \frac{1}{2}-a, \frac{1}{2}+b, \frac{1}{2}-b \\ \frac{1}{2}, 1-c, 1+c \end{smallmatrix} \middle| \frac{z^2}{4(z-1)}\right) \\ \frac{abc}{(\frac{1}{2}+c)(\frac{1}{2}-c)} \frac{z}{(1-z)^{1+a}} {}_4F_3\left(\begin{smallmatrix} 1+a, 1-a, 1+b, 1-b \\ \frac{3}{2}, \frac{3}{2}+c, \frac{3}{2}-c \end{smallmatrix} \middle| \frac{z^2}{4(z-1)}\right) \end{array} \right) = \left(\begin{array}{c} \frac{1}{2} \\ \frac{1}{2} \end{array} \right) \left(\begin{array}{c} {}_2F_1\left(\begin{smallmatrix} \frac{1}{2}+a+c, \frac{1}{2}+b+c \\ 1+2c \end{smallmatrix} \middle| z\right){}_2F_1\left(\begin{smallmatrix} \frac{1}{2}+a-c, \frac{1}{2}-b-c \\ 1-2c \end{smallmatrix} \middle| z\right) \\ {}_2F_1\left(\begin{smallmatrix} \frac{1}{2}+a+c, \frac{1}{2}-b+c \\ 1+2c \end{smallmatrix} \middle| z\right){}_2F_1\left(\begin{smallmatrix} \frac{1}{2}+a-c, \frac{1}{2}+b-c \\ 1-2c \end{smallmatrix} \middle| z\right) \end{array} \right)$$

Corollary 7.21. (${}_2E_3 = {}_1E_1 \otimes {}_1E_1$):

$${}_2F_3\left(\begin{smallmatrix} a, b-a \\ b, \frac{b}{2}, \frac{b+1}{2} \end{smallmatrix} \middle| \frac{z^2}{4}\right) = {}_1F_1\left(\begin{smallmatrix} a \\ b \end{smallmatrix} \middle| -z\right){}_1F_1\left(\begin{smallmatrix} a \\ b \end{smallmatrix} \middle| z\right)$$

$$\left(\begin{array}{c} {}_2F_3\left(\begin{smallmatrix} \frac{1}{2}+a, \frac{1}{2}-a \\ \frac{1}{2}, 1-b, 1+b \end{smallmatrix} \middle| \frac{z^2}{4}\right) \\ \frac{abz}{(\frac{1}{2}+b)(\frac{1}{2}-b)} {}_2F_3\left(\begin{smallmatrix} \frac{3}{2}, \frac{3}{2}+b, \frac{3}{2}-b \\ \frac{1}{2}+a, 1-a \end{smallmatrix} \middle| \frac{z^2}{4}\right) \end{array} \right) = \left(\begin{array}{c} \frac{1}{2} \\ \frac{1}{2} \end{array} \right) \left(\begin{array}{c} {}_1F_1\left(\begin{smallmatrix} \frac{1}{2}+a+b \\ 1+2b \end{smallmatrix} \middle| -z\right){}_1F_1\left(\begin{smallmatrix} \frac{1}{2}+a-b \\ 1-2b \end{smallmatrix} \middle| z\right) \\ {}_1F_1\left(\begin{smallmatrix} \frac{1}{2}+a+b \\ 1+2c \end{smallmatrix} \middle| z\right){}_1F_1\left(\begin{smallmatrix} \frac{1}{2}+a-b \\ 1-2b \end{smallmatrix} \middle| -z\right) \end{array} \right)$$

$${}_4F_1\left(\begin{smallmatrix} a, b, \frac{a+b}{2}, \frac{1+a+b}{2} \\ a+b \end{smallmatrix} \middle| 4z^2\right) = {}_2F_0(a, b | -z){}_2F_0(a, b | z)$$

$${}_2U_3\left(\begin{smallmatrix} 1-a-b, a+b \\ \frac{1}{2}, 1+a-b, 1-a+b \end{smallmatrix} \middle| z\right) = {}_2F_0(1-2a, 1-2b | z){}_2F_0(2a, 2b | z)$$

7.7 Evaluations at $z = \pm 1$ etc.

For many purposes, a plain evaluation of ${}_pF_{p-1}(1)$ is less useful than the v_0, \dots, v_{p-2} of (2.3). It is also not necessary to state any tedious convergence criteria when giving these v_i . At a non-singular point, the first p Taylor coefficients are useful.

Theorem 7.22.

$${}_2F_1\left(\begin{smallmatrix} a, b \\ a-b+1 \end{smallmatrix} \middle| x-1\right) = \frac{\Gamma(\frac{1}{2})\Gamma(a-b+1)}{2^{a+1}} \left(\frac{ax+2}{\Gamma(\frac{a+1}{2})\Gamma(\frac{a+2}{2}-b)} - \frac{2x}{\Gamma(\frac{a}{2})\Gamma(\frac{a+1}{2}-b)} \right) + O(x^2)$$

Theorem 7.23.

$$\begin{aligned} {}_3F_2\left(\begin{smallmatrix} 2a, 2b, c-\frac{1}{2} \\ a+b+\frac{1}{2}, 2c-1 \end{smallmatrix} \middle| 1-x\right) &= \frac{\Gamma(a+b+\frac{1}{2})\Gamma(2c-1)\Gamma(a+b-c)}{\Gamma(2a)\Gamma(2b)\Gamma(c-\frac{1}{2})} x^{c-a-b} (1 + O(x)) \\ &\quad - \Gamma(\frac{1}{2})\Gamma(c)\Gamma(a+b+\frac{1}{2})\Gamma(c-a-b-1) \left(\frac{2x}{\Gamma(a)\Gamma(b)\Gamma(c-a-\frac{1}{2})\Gamma(c-b-\frac{1}{2})} + \frac{a+b-c+1+2abx}{\Gamma(a+\frac{1}{2})\Gamma(b+\frac{1}{2})\Gamma(c-a)\Gamma(c-b)} + O(x^2) \right), \\ (1-x)^{\frac{1}{2}-a-b} {}_3F_2\left(\begin{smallmatrix} \frac{1}{2}+a-b, \frac{1}{2}-a+b, c-a-b \\ \frac{3}{2}-a-b, 2c-a-b-\frac{1}{2} \end{smallmatrix} \middle| 1-x\right) &= \frac{\Gamma(\frac{3}{2}-a-b)\Gamma(2c-a-b-\frac{1}{2})\Gamma(a+b-c)}{\Gamma(\frac{1}{2}+a-b)\Gamma(\frac{1}{2}-a+b)\Gamma(c-a-b)} x^{c-a-b} (1 + O(x)) \\ &\quad + 2^{2a+2b-2c+1} \frac{\pi\Gamma(\frac{3}{2}-a-b)\Gamma(2c-a-b-\frac{1}{2})}{a+b-c+1} \left(\frac{2x}{\Gamma(\frac{1}{2}-a)\Gamma(\frac{1}{2}-b)\Gamma(c-a-\frac{1}{2})\Gamma(c-b-\frac{1}{2})} + \frac{a+b-c+1+2abx}{\Gamma(1-a)\Gamma(1-b)\Gamma(c-a)\Gamma(c-b)} + O(x^2) \right). \end{aligned}$$

7.8 Multiple integral evaluations

Remark 7.24. The following conversions from ${}_2F_1(\frac{1}{2}, \frac{1}{2}; 1|z)$ for $\Re z > \frac{1}{2}$ are not done correctly in the integral evaluations, so the range of validity is reduced for the ${}_2F_1(\frac{1}{4}, \frac{1}{4}; 1)$ expressions.

$$\begin{aligned} {}_2F_1\left(\frac{1}{4}, \frac{1}{4}; 1|z\right) &= {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{2} - \frac{\sqrt{1-z}}{2}\right), \\ \frac{4\sqrt{\pi}}{\Gamma(\frac{1}{4})^2} \sqrt{1-z} {}_2F_1\left(\frac{3}{4}, \frac{3}{4}; \frac{3}{2}|1-z\right) + {}_2F_1\left(\frac{1}{4}, \frac{1}{4}; 1|z\right) &= {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{2} + \frac{\sqrt{1-z}}{2}\right), \\ {}_2F_1\left(\frac{1}{4}, \frac{3}{4}; 1|z\right) &= (1-z)^{-1/4} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{2} - \frac{1}{2\sqrt{1-z}}\right) \\ \sqrt{2} {}_2F_1\left(\frac{1}{4}, \frac{3}{4}; 1|1-z\right) \pm i {}_2F_1\left(\frac{1}{4}, \frac{3}{4}; 1|z\right) &= (1-z)^{-1/4} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{2} + \frac{1}{2\sqrt{1-z}}\right) \end{aligned}$$

Theorem 7.25. Rank 2:

$$\frac{1}{\pi^2} \iint_0^\pi \frac{du dv}{1-a \cos u - b \cos v - c \cos u \cos v} = \frac{1}{\sqrt{1+a-b+c}\sqrt{1-a+b+c}} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; 1 - \frac{(1+a+b-c)(1-a-b-c)}{(1+a-b+c)(1-a+b+c)}\right)$$

Theorem 7.26. Rank 3:

$$\frac{1}{\pi^3} \iiint_0^\pi \frac{du dv dw}{1-a \cos u \cos v \cos w} = {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1-\sqrt{1-a^2}}{2}\right)^2 = {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{a}{2} \frac{\sqrt{1+a}-\sqrt{1-a}}{\sqrt{1+a}+\sqrt{1-a}}\right)^2 = {}_2F_1\left(\frac{1}{4}, \frac{1}{4}; 1|a^2\right)^2$$

equivalent to ${}_3F_2(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}; \frac{1}{1,1}|z) = {}_2F_1(\frac{1}{2}, \frac{1}{2}; \frac{1-\sqrt{1-z}}{2})^2$.

Theorem 7.27. Rank 4:

$$\begin{aligned} \frac{1}{\pi^3} \iiint_0^\pi \frac{du dv dw}{1-a \cos v \cos w - b \cos u \cos w} &= F_4\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{1,1}|a^2, b^2\right) \\ &= \prod_{a \leftrightarrow b} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1+a^2-b^2-\sqrt{(1-a^2+b^2)^2-4b^2}}{2}\right) \\ &= \prod_{a \leftrightarrow b} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{1}|a \frac{\sqrt{1+a-b}\sqrt{1+a+b}-\sqrt{1-a-b}\sqrt{1-a+b}}{\sqrt{1+a-b}\sqrt{1+a+b}+\sqrt{1-a-b}\sqrt{1-a+b}}\right) \\ &= \prod_{a \leftrightarrow b} {}_2F_1\left(\frac{1}{4}, \frac{1}{4}; \frac{1}{1}|4ab \frac{(a+b)\sqrt{1+a-b}\sqrt{1-a+b}+(a-b)\sqrt{1+a+b}\sqrt{1-a-b}}{(a+b)\sqrt{1+a-b}\sqrt{1-a+b}-(a-b)\sqrt{1+a+b}\sqrt{1-a-b}}\right) \end{aligned}$$

with the corollary ${}_4F_3(\frac{1}{4}, \frac{1}{4}, \frac{3}{4}, \frac{3}{4}; \frac{3}{2,1,1}|z) = {}_2F_1(\frac{1}{2}, \frac{1}{2}; \frac{1+\sqrt{-z}-\sqrt{1-z}}{2}) {}_2F_1(\frac{1}{2}, \frac{1}{2}; \frac{1-\sqrt{-z}-\sqrt{1-z}}{2})$ (also by Theorem 7.20).

The conjecture at the end of Glasser and Zucker 1977 “Extended Watson integrals for the cubic lattices” seems to be false as the rank seemingly increases to 5 in the obvious (a, b, c) generalizations of the following.

Theorem 7.28. Rank 4:

$$\begin{aligned} \frac{1}{\pi^3} \iiint_0^\pi \frac{du dv dw}{1-a \cos v \cos w - \frac{1}{2}b \cos u \cos w - \frac{1}{2}b \cos u \cos v} &= \frac{1}{1+a} F_4\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{1,1}|\left(\frac{2\sqrt{a}+\sqrt{4a+b^2}}{2(a+1)}\right)^2, \left(\frac{2\sqrt{a}-\sqrt{4a+b^2}}{2(a+1)}\right)^2\right) \\ &= \frac{1}{1+a} \prod_{\pm} {}_2F_1\left(\frac{1}{2}, \frac{1}{2}; \frac{1}{2} - \frac{(1-a)\sqrt{1-a+b}\sqrt{1-a-b}}{2(1+a)^2} \pm \frac{\sqrt{a}\sqrt{4a+b^2}}{(1+a)^2}\right) \\ &= \frac{1}{1+a} \prod_{\pm} {}_2F_1\left(\frac{1}{4}, \frac{1}{4}; \frac{1}{1}|\frac{b^2}{(1+a)^2} \frac{(1-a)\sqrt{4a+b^2} \mp 2\sqrt{a}\sqrt{1-a+b}\sqrt{1-a-b}}{(1-a)\sqrt{4a+b^2} \pm 2\sqrt{a}\sqrt{1-a+b}\sqrt{1-a-b}}\right) \end{aligned}$$

The special case $b = 2a$ is recorded by Glasser (quoting Iwata) in the second form.

Proof. Use Theorem 7.25 for the $\mathrm{d}u\mathrm{d}w$ integral, substitute $\cos \theta = 1 - 2t$, then expand and apply a quadratic transformation of the ${}_2F_1$ to get to a polynomial where Theorem 7.1 can be used to get to an F_4 to which Theorem 7.16 applies.

$$\begin{aligned}
\frac{1}{1+a} \int_0^\pi {}_2F_1\left(\frac{1}{2}, \frac{1}{2} \mid \frac{4a+b^2 \cos^2 u}{(1+a)^2} u\right) \frac{\mathrm{d}u}{\pi} &= \frac{1}{1+a} \int_0^\pi {}_2F_1\left(\frac{1}{2}, \frac{1}{2} \mid \frac{8a+b^2+b^2 \cos \theta}{2(1+a)^2}\right) \frac{\mathrm{d}\theta}{\pi} \\
&= \frac{1}{1+a} \sum_{n=0}^{\infty} \frac{(\frac{1}{2})_n^2}{n!^2} \int_0^1 \left(\frac{4a+b^2-b^2 t}{(1+a)^2}\right)^n \frac{\mathrm{d}t}{\pi \sqrt{t} \sqrt{1-t}} \\
&= \frac{1}{1+a} \sum_{n=0}^{\infty} \frac{(\frac{1}{2})_n^2}{n!^2} \left(\frac{4a+b^2}{(1+a)^2}\right)^n {}_2F_1\left(-n, \frac{1}{2} \mid \frac{b^2}{4a+b^2}\right) \\
&= \frac{1}{1+a} \sum_{n=0}^{\infty} \frac{(\frac{1}{2})_n^2}{n!^2} \left(\frac{2\sqrt{a}+\sqrt{4a+b^2}}{2(1+a)}\right)^{2n} {}_2F_1\left(-n, -n \mid \left(\frac{2\sqrt{a}-\sqrt{4a+b^2}}{2\sqrt{a}+\sqrt{4a+b^2}}\right)^2\right)
\end{aligned}$$

□

Theorem 7.29. Rank 4: with $x = \frac{1-a^2+b^2-\sqrt{1-a-b}\sqrt{1+a-b}\sqrt{1-a+b}\sqrt{1+a+b}}{1+a^2-b^2+\sqrt{1-a-b}\sqrt{1+a-b}\sqrt{1-a+b}\sqrt{1+a+b}}$ (i.e. $x = (1+x)(b^2 + a^2x)$),

$$\begin{aligned}
\frac{1}{\pi^3} \iiint_0^\pi \frac{\mathrm{d}u \mathrm{d}v \mathrm{d}w}{1-a \cos u - \frac{1}{2}b \cos v - \frac{1}{2}b \cos w} &= \frac{1}{\sqrt{1-a^2+b^2}} F_4\left(\frac{1}{4}, \frac{3}{4} \mid \left(\frac{b+b\sqrt{1-a^2}}{1-a^2+b^2}\right)^2, \left(\frac{b-b\sqrt{1-a^2}}{1-a^2+b^2}\right)^2\right) \\
&= \frac{\sqrt{x}}{b} F_4\left(\frac{1}{2}, \frac{1}{2} \mid -x\left(\frac{b+\sqrt{a^2x+b^2}}{2b}\right)^2, -x\left(\frac{b-\sqrt{a^2x+b^2}}{2b}\right)^2\right) \\
&= \frac{\sqrt{x}}{b} \prod_{\pm} {}_2F_1\left(\frac{1}{2}, \frac{1}{2} \mid \frac{1}{2} - \frac{\sqrt{1+x}\sqrt{b^2+b^2x+a^2x^2}}{2b} \pm \frac{x\sqrt{b^2+a^2x}}{2b}\right) \\
&= \frac{\sqrt{x}}{b} \prod_{\pm} {}_2F_1\left(\frac{1}{4}, \frac{3}{4} \mid -x^2\left(\frac{1 \pm \sqrt{1-a^2}}{b}\right)^2\right) \\
&= \frac{2\sqrt{1+x}\sqrt{b^2+a^2x}}{\sqrt{2b^2+2b^2x+a^2x^2+2b\sqrt{1+x}\sqrt{b^2+b^2x+a^2x^2}}} \prod_{\pm} {}_2F_1\left(\frac{1}{2}, \frac{1}{2} \mid \frac{\sqrt{1+x}\sqrt{b^2+b^2x+a^2x^2} \pm x\sqrt{b^2+a^2x-b}}{\sqrt{1+x}\sqrt{b^2+b^2x+a^2x^2} \pm x\sqrt{b^2+a^2x+b}}\right)
\end{aligned}$$

The special case $b = 2a$ is recorded by Glasser (quoting Joyce) in the last form.

7.9 contiguous

Recall $\theta = z \frac{\partial}{\partial z}$. The last row of these matrices follows from the hypergeometric differential equation.

$$\begin{aligned}
\begin{pmatrix} 1 \\ \theta \end{pmatrix} {}_2F_1\left(\begin{smallmatrix} a_1+1, a_2 \\ b_1+1 \end{smallmatrix} \mid z\right) &= \begin{pmatrix} 1 & \frac{1}{a_1} \\ \frac{a_1 a_2 z}{a_1(1-z)} & \frac{a_2 z + a_1 - b_1}{a_1(1-z)} \end{pmatrix} \begin{pmatrix} 1 \\ \theta \end{pmatrix} {}_2F_1\left(\begin{smallmatrix} a_1, a_2 \\ b_1+1 \end{smallmatrix} \mid z\right) \\
\begin{pmatrix} 1 \\ \theta \end{pmatrix} {}_2F_1\left(\begin{smallmatrix} a_1, a_2 \\ b_1 \end{smallmatrix} \mid z\right) &= \begin{pmatrix} 1 & \frac{1}{b_1} \\ \frac{a_1 a_2 z}{b_1(1-z)} & \frac{(a_1+a_2-b_1)z}{b_1(1-z)} \end{pmatrix} \begin{pmatrix} 1 \\ \theta \end{pmatrix} {}_2F_1\left(\begin{smallmatrix} a_1, a_2 \\ b_1+1 \end{smallmatrix} \mid z\right) \\
\begin{pmatrix} 1 \\ \theta \\ \theta^2 \end{pmatrix} {}_3F_2\left(\begin{smallmatrix} a_1+1, a_2, a_3 \\ b_1+1, b_2+1 \end{smallmatrix} \mid z\right) &= \begin{pmatrix} 1 & \frac{1}{a_1} & 0 \\ 0 & 1 & \frac{1}{a_1} \\ \frac{a_1 a_2 a_3 z}{a_1(1-z)} & \frac{(a_2 a_3 + a_1 a_3 + a_1 a_2)z - b_1 b_2}{a_1(1-z)} & \frac{(a_2+a_3)z + a_1 - b_1 - b_2}{a_1(1-z)} \end{pmatrix} \begin{pmatrix} 1 \\ \theta \\ \theta^2 \end{pmatrix} {}_3F_2\left(\begin{smallmatrix} a_1, a_2, a_2 \\ b_1+1, b_2+1 \end{smallmatrix} \mid z\right) \\
\begin{pmatrix} 1 \\ \theta \\ \theta^2 \end{pmatrix} {}_3F_2\left(\begin{smallmatrix} a_1, a_2, a_3 \\ b_1, b_2+1 \end{smallmatrix} \mid z\right) &= \begin{pmatrix} 1 & \frac{1}{b_1} & 0 \\ 0 & 1 & \frac{1}{b_1} \\ \frac{a_1 a_2 a_3 z}{b_1(1-z)} & \frac{(a_2 a_3 + a_1 a_3 + a_1 a_2)z - b_1 b_2}{b_1(1-z)} & \frac{(a_1+a_2+a_3-b_1)z - b_2}{b_1(1-z)} \end{pmatrix} \begin{pmatrix} 1 \\ \theta \\ \theta^2 \end{pmatrix} {}_3F_2\left(\begin{smallmatrix} a_1, a_2, a_3 \\ b_1+1, b_2+1 \end{smallmatrix} \mid z\right)
\end{aligned}$$

The pattern continues and the inverse of these matrices also consist of degree 1 polynomials z . We can:

1. increment a numerator parameter by 1 a long as it didn't start at 0
2. decrement a denominator parameter as long as it doesn't end up at 0
3. decrement a numerator parameter as long as it doesn't end up at a denominator parameter
4. increment a denominator parameter as long as it didn't start at a numerator parameter

Theorem 7.30. *Let \mathbf{m} and \mathbf{n} be integer vectors. There exists a matrix M of rational functions in z of degree bounded by $\sum |\mathbf{m}| + \sum |\mathbf{n}|$ (?) such that*

$$(1 \theta \dots \theta^{p-1})^\top {}_pF_{p-1}(\mathbf{a} + \mathbf{m} | z) = M(1 \theta \dots \theta^{p-1})^\top {}_pF_{p-1}(\mathbf{a} | z)$$

thus any $p + 1$ such contiguous functions are linearly dependent over $\mathbb{C}(z)$.

7.10 misc

$$(a - b) {}_1F_2(\frac{1}{1+a}, \frac{1}{1+b} | z) = a {}_0F_1(\frac{1}{1+a-b} | z) {}_1F_2(\frac{b}{1+b}, \frac{1}{1+b-a} | z) - b {}_0F_1(\frac{1}{1+b-a} | z) {}_1F_2(\frac{a}{1+a}, \frac{1}{1+a-b} | z)$$

8 ${}_0F_1$, ${}_1F_1$ and ${}_2F_0$

This includes all Bessel functions, Airy functions, and confluent functions, and one confusing aspect of these cases is that the ${}_pU_q$ series are themselves hypergeometric.

$$\begin{aligned} {}_0U_1(b_1 | z) &= {}_2F_0\left(-\frac{1}{2} + b_1, \frac{3}{2} - b_1 \middle| \frac{1}{2}z\right), \\ {}_1U_1(a_1; b_1 | z) &= {}_2F_0(1 - a_1, b_1 - a_1 | z), \end{aligned}$$

which are generalized slightly via

$$\begin{aligned} {}_1U_2(1; b_1, b_2 | z) &= {}_2F_0\left(\frac{1}{2} + b_1 - b_2, \frac{1}{2} + b_2 - b_1 \middle| \frac{1}{2}z\right), \\ {}_2U_2(a_1, 1; b_1, b_2 | z) &= {}_2F_0(b_1 - a_1, b_2 - a_1 | z). \end{aligned} \tag{8.1}$$

8.1 ${}_0F_1$

As a consequence of (4.5), we have, for example,

$$2\sqrt{\pi} z^{\frac{1}{4} + \frac{b}{2}} \frac{{}_0F_1(1 + b | z)}{\Gamma(1 + b)} = e^{2\sqrt{z}} {}_2F_0\left(\frac{1}{2} + b, \frac{1}{2} - b \middle| \frac{1}{4\sqrt{z}}\right) + e^{\pm \pi i (\frac{1}{2} - b)} e^{-2\sqrt{z}} {}_2F_0\left(\frac{1}{2} + b, \frac{1}{2} - b \middle| \frac{-1}{4\sqrt{z}}\right).$$

This means the various Bessel functions defined by

$$\begin{aligned} I_\nu(2z) &= \frac{z^\nu {}_0F_1(1 + \nu | z^2)}{\Gamma(1 + \nu)}, \\ K_\nu(2z) &= -\frac{\pi}{2 \sin \pi \nu} \frac{z^\nu {}_0F_1(1 + \nu | z^2)}{\Gamma(1 + \nu)} + \frac{\pi}{2 \sin \pi \nu} \frac{z^{-\nu} {}_0F_1(1 - \nu | z^2)}{\Gamma(1 - \nu)}, \\ J_\nu(2z) &= \frac{z^\nu {}_0F_1(1 + \nu | -z^2)}{\Gamma(1 + \nu)}, \\ Y_\nu(2z) &= \frac{\cos \pi \nu}{\sin \pi \nu} \frac{z^\nu {}_0F_1(1 + \nu | -z^2)}{\Gamma(1 + \nu)} - \frac{1}{\sin \pi \nu} \frac{z^{-\nu} {}_0F_1(1 - \nu | -z^2)}{\Gamma(1 - \nu)}, \end{aligned}$$

have the following ${}_2F_0$ representations for $z \neq 0$ (recall $\pm = (\log(z) - \log(-z))/(\pi i)$).

$$\begin{aligned} I_{\nu-\frac{1}{2}}(z) &= \frac{e^{\pm \pi i \nu} e^{-z}}{\sqrt{2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{-1}{2z}) + \frac{e^z}{\sqrt{2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{1}{2z}), \\ K_{\nu-\frac{1}{2}}(z) &= \frac{e^{-z}}{\sqrt{2z/\pi}} {}_2F_0(\nu, 1 - \nu | \frac{-1}{2z}), \\ J_{\nu-\frac{1}{2}}(z) &= \frac{e^{\pm \pi i \frac{\nu}{2} \mp i z}}{\sqrt{2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{\pm i}{2z}) + \frac{z^{2\nu}}{(z^2)^\nu} \frac{e^{\mp \pi i \frac{\nu}{2} \pm i z}}{\sqrt{2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{\mp i}{2z}), \\ Y_{\nu-\frac{1}{2}}(z) &= \frac{e^{\pm \pi i \frac{\nu}{2} \mp i z}}{\sqrt{-2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{\pm i}{2z}) - (2 - \frac{z^{2\nu}}{(z^2)^\nu}) \frac{e^{\mp \pi i \frac{\nu}{2} \pm i z}}{\sqrt{-2\pi z}} {}_2F_0(\nu, 1 - \nu | \frac{\mp i}{2z}). \end{aligned}$$

These last two are slightly cleaner in the equivalent form with $H_\nu^{(i)}(z) = J_\nu(z) - (-1)^i Y_\nu(z)$

$$\sqrt{\frac{\pi z}{2}} \begin{pmatrix} e^{-i(z-\frac{\pi\nu}{2})} H_{\nu-\frac{1}{2}}^{(1)}(z) \\ e^{+i(z-\frac{\pi\nu}{2})} H_{\nu-\frac{1}{2}}^{(2)}(z) \end{pmatrix} = \begin{Bmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & \frac{-\pi}{2} < \arg z \leq \frac{\pi}{2} \\ \begin{pmatrix} 1 & 0 \\ 2i \sin(\pi\nu) e^{2iz} & 1 \end{pmatrix}, & \arg z > \frac{\pi}{2} \\ \begin{pmatrix} 1 & -2i \sin(\pi\nu) e^{-2iz} \\ 0 & 1 \end{pmatrix}, & \arg z \leq \frac{-\pi}{2} \end{Bmatrix} \begin{pmatrix} {}_2F_0(\nu, 1 - \nu | \frac{-i}{2z}) \\ {}_2F_0(\nu, 1 - \nu | \frac{i}{2z}) \end{pmatrix},$$

which we recognize simply as a different branch (8.3) of the ${}_2F_0$ s, matching the branch of the l.h.s. As long as $\arg z \neq \pi$, the correction matrices differ from the identity by an exponentially small amount.

8.1.1 parameter derivative

$\frac{\partial}{\partial b} {}_0F_1(b|z)$ satisfies an inhomogenous ${}_0E_1(b|z)$ equation. Using the method of variation of parameters and Theorem 7.18 to evaluate the integrals produces

$$\begin{aligned} \frac{\partial}{\partial b} {}_0F_1(1+b|z) &= (\frac{1}{2b} + \frac{z}{1-b^2} {}_3F_4(\frac{1,1,\frac{3}{2}}{2,2,2-b,2+b}|4z)) {}_0F_1(1+b|z) - \frac{1}{2b} {}_2F_3(\frac{b,\frac{1}{2}+b}{1+b,1+b,1+2b}|4z) {}_0F_1(1-b|z), \\ \frac{\partial}{\partial b} {}_2F_0(\frac{1}{2}+b, \frac{1}{2}-b|z) &= -2bz {}_4F_1(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}+b, \frac{1}{2}-b | \frac{3}{2} | 4z^2) {}_2F_0(\frac{1}{2}+b, \frac{1}{2}-b|z) - 2bz^2 {}_2U_3(\frac{b,\frac{1}{2}+b}{1+b,1+b,1+2b}|z) {}_2F_0(\frac{1}{2}+b, \frac{1}{2}-b|-z). \end{aligned}$$

8.1.2 integral evaluations

The first here follows from (10.2) and the second from the first.

$$\begin{aligned} \frac{1}{2\pi i} \int_{-\infty}^{(0+)} \frac{e^{t+\frac{z}{t}}}{t^{1+b}} dt &= \frac{{}_0F_1(1+b|z)}{\Gamma(1+b)} \\ \int_0^\infty \frac{e^{-\frac{z}{t}-zt}}{t^{1+b}} dt &= \Gamma(b) z^{-b} {}_0F_1(1-b|z^2) + \Gamma(-b) z^b {}_0F_1(1+b|z^2) \\ \int_0^\infty \frac{e^{-\frac{z_1}{t}-z_2t}}{t^{1+b}} dt &= \Gamma(b) z_1^{-b} {}_0F_1(1-b|z_1 z_2) + \Gamma(-b) z_2^b {}_0F_1(1+b|z_1 z_2) \end{aligned}$$

The last two only converge as written for restricted $z \neq 0$. The integrals can converge everywhere if the approach to the end points is twisted accordingly. The following are direct calculations combined with (3.1), and $a = \frac{1}{2}$ is the case of interest.

$$\begin{aligned}
& \frac{2}{\Gamma(\frac{1}{2})\Gamma(1-a+b)} \int_0^1 e^{-2zt} t^{2a-1} (1-t^2)^{b-a} dt = \frac{\Gamma(a)}{\Gamma(\frac{1}{2})\Gamma(1+b)} {}_1F_2\left(\frac{a}{\frac{1}{2}, 1+b} \middle| z^2\right) - \frac{\Gamma(\frac{1}{2}+a)}{\Gamma(\frac{3}{2})\Gamma(\frac{3}{2}+b)} z {}_1F_2\left(\frac{\frac{1}{2}+a}{\frac{3}{2}, \frac{3}{2}+b} \middle| z^2\right), \\
& \frac{2}{\Gamma(\frac{1}{2})\Gamma(1-a+b)} \int_0^\infty e^{-2zt} t^{2a-1} (1+t^2)^{b-a} dt = \frac{\Gamma(a)\Gamma(\frac{1}{2}+a)}{\pi\Gamma(1-a+b)} z^{-2a} {}_3F_0\left(a-b, a, \frac{1}{2}+a \middle| \frac{-1}{z^2}\right) \\
& = \frac{\Gamma(b)\Gamma(\frac{1}{2}+b)}{\pi\Gamma(1-a+b)} z^{-2b} {}_1F_2\left(\frac{a-b}{\frac{1}{2}-b, 1-b} \middle| -z^2\right) - \frac{\sin\pi(a-b)}{\sin\pi b} \frac{\Gamma(a)}{\Gamma(\frac{1}{2})\Gamma(1+b)} {}_1F_2\left(\frac{a}{\frac{1}{2}, 1+b} \middle| -z^2\right) + \frac{\sin\pi(a-b)}{\cos\pi b} \frac{\Gamma(\frac{1}{2}+a)}{\Gamma(\frac{3}{2})\Gamma(\frac{3}{2}+b)} z {}_1F_2\left(\frac{\frac{1}{2}+a}{\frac{3}{2}, \frac{3}{2}+b} \middle| -z^2\right), \\
& \frac{2}{\Gamma(\frac{1}{2})\Gamma(1-a+b)} \int_1^\infty e^{-2zt} t^{2a-1} (t^2-1)^{b-a} dt \\
& = \frac{\Gamma(b)\Gamma(\frac{1}{2}+b)}{\pi\Gamma(1-a+b)} z^{-2b} {}_1F_2\left(\frac{a-b}{\frac{1}{2}-b, 1-b} \middle| z^2\right) - \frac{\sin\pi a}{\sin\pi b} \frac{\Gamma(a)}{\Gamma(\frac{1}{2})\Gamma(1+b)} {}_1F_2\left(\frac{a}{\frac{1}{2}, 1+b} \middle| z^2\right) + \frac{\cos\pi a}{\cos\pi b} \frac{\Gamma(\frac{1}{2}+a)}{\Gamma(\frac{3}{2})\Gamma(\frac{3}{2}+b)} z {}_1F_2\left(\frac{\frac{1}{2}+a}{\frac{3}{2}, \frac{3}{2}+b} \middle| z^2\right).
\end{aligned}$$

These “squared” formulas should be compared with the non-squared version next. The three integrals are linearly dependent as $I_2(\mathbf{i}z) = e^{-\mathbf{i}\pi a} I_1(z) + e^{-\mathbf{i}\pi b} I_3(z)$.

8.2 ${}_1F_1$ and ${}_2F_0$

As before, $I_2(-z) = e^{-\mathbf{i}\pi a} I_1(z) + e^{-\mathbf{i}\pi b} I_3(z)$, for

$$\begin{aligned}
& \frac{1}{\Gamma(1-a+b)} \int_0^1 e^{-zt} t^{a-1} (1-t)^{b-a} dt = \frac{\Gamma(a)}{\Gamma(1+b)} {}_1F_1\left(\frac{a}{1+b} \middle| -z\right), \\
& \frac{1}{\Gamma(1-a+b)} \int_0^\infty e^{-zt} t^{a-1} (1+t)^{b-a} dt = \frac{\Gamma(a)}{\Gamma(1-a+b)} z^{-a} {}_2F_0\left(a-b, a \middle| \frac{-1}{z}\right) \\
& = \frac{\Gamma(b)}{\Gamma(1-a+b)} z^{-b} {}_1F_1\left(\frac{a-b}{1-b} \middle| z\right) - \frac{\sin\pi(a-b)}{\sin\pi b} \frac{\Gamma(a)}{\Gamma(1+b)} {}_1F_1\left(\frac{a}{1+b} \middle| z\right), \\
& \frac{1}{\Gamma(1-a+b)} \int_1^\infty e^{-zt} t^{a-1} (t-1)^{b-a} dt = e^{-z} z^{a-b-1} {}_2F_0\left(1-a, 1-a+b \middle| \frac{-1}{z}\right) \\
& = \frac{\Gamma(b)}{\Gamma(1-a+b)} z^{-b} {}_1F_1\left(\frac{a-b}{1-b} \middle| -z\right) - \frac{\sin\pi a}{\sin\pi b} \frac{\Gamma(a)}{\Gamma(1+b)} {}_1F_1\left(\frac{a}{1+b} \middle| -z\right).
\end{aligned}$$

For $s = +$ or $-$, we will set $U_s(\frac{a}{b}|z) = (sz)^{-a} {}_2F_0(a, 1+a-b|\frac{-1}{z})$ with $s = +$ being the default. $f(z) = {}_1F_1(a; b|z)$ satisfies (along with $z^{1-b} {}_1F_1(1-b+a; 2-b|z)$ and $U(\frac{a}{b}|z)$ and $e^z U(\frac{b-a}{b}|z)$)

$$f''(z) - (1 - \frac{b}{z})f'(z) - \frac{a}{z}f(z) = 0.$$

$f(z) = {}_2F_0(a, b|\frac{-1}{z})$ satisfies (along with $e^z z^{a+b-1} {}_2F_0(1-a, 1-b|\frac{1}{z})$)

$$f''(z) - (1 + \frac{a+b-1}{z})f'(z) + \frac{ab}{z^2}f(z) = 0.$$

with the various connection formulas taking the form

$$\begin{aligned}
{}_2F_0(a, b|\frac{-1}{z}) &= \frac{\Gamma(b-a)}{\Gamma(b)} z^a {}_1F_1\left(\frac{a}{1+a-b} \middle| z\right) + \frac{\Gamma(a-b)}{\Gamma(a)} z^b {}_1F_1\left(\frac{b}{1+b-a} \middle| z\right) \\
e^z (-z)^{a+b-1} {}_2F_0(1-a, 1-b|\frac{1}{z}) &= \frac{\Gamma(b-a)}{\Gamma(1-a)} (-z)^a {}_1F_1\left(\frac{a}{1+a-b} \middle| z\right) + \frac{\Gamma(a-b)}{\Gamma(1-b)} (-z)^b {}_1F_1\left(\frac{b}{1+b-a} \middle| z\right) \\
{}_1F_1(\frac{a}{b}|z) &= e^z {}_1F_1\left(\frac{b-a}{b} \middle| -z\right), \\
\frac{1}{\Gamma(b)} {}_1F_1(\frac{a}{b}|z) &= \frac{(-z)^{-a}}{\Gamma(b-a)} {}_2F_0(a, 1+a-b, \frac{-1}{z}) + \frac{e^z z^{a-b}}{\Gamma(a)} {}_2F_0(b-a, 1-a, \frac{1}{z}), \\
&= \frac{1}{\Gamma(b-a)} U_-(\frac{a}{b}|z) + \frac{1}{\Gamma(a)} e^z U_-(\frac{b-a}{b}|z)
\end{aligned} \tag{8.2}$$

This connection formula says that the following vector is multiplied by the following matrix as z crosses the negative real axis (resp. positive real axis).

$$\begin{pmatrix} {}_2F_0(a, b|\frac{-1}{z}) \\ e^z (-z)^{a+b-1} {}_2F_0(1-a, 1-b|\frac{1}{z}) \end{pmatrix} : \begin{pmatrix} 1 & \frac{2\pi\mathbf{i}}{\Gamma(a)\Gamma(b)} \\ 0 & 1 \end{pmatrix}, \text{ resp. } \begin{pmatrix} 1 & 0 \\ \frac{-2\pi\mathbf{i}e^{\pi\mathbf{i}(a+b)}}{\Gamma(1-a)\Gamma(1-b)} & e^{2\pi\mathbf{i}(a+b)} \end{pmatrix}. \tag{8.3}$$

8.3 solution of ${}_1F_1$ equation around 0

8.3.1 case $b \notin \mathbb{Z}$

We can assume wlog we are simply calculating ${}_1F_1(a; b|z) = \sum c_k z^k$ and possibly its derivative. Set $c'_k := (k+1)c_{k+1}$. With $M_0 = I$ and

$$M_k = \frac{1}{k} \begin{pmatrix} 0 & 1 \\ 0 & \frac{a+k}{b+k} \end{pmatrix} M_{k-1},$$

we have $\begin{pmatrix} f(z) \\ f'(z) \end{pmatrix} = S \begin{pmatrix} c_0 \\ c'_0 \end{pmatrix}$ where $S = \sum_{k=0}^{\infty} M_k z^k$.

The first row of S is annihilated by the operator

$$\theta(\theta + b - 1) - (\theta + a - 1)z = (\theta + b - 1)(\theta - \frac{\theta+a-1}{\theta+b-1}z),$$

and the residual for truncation at n is given by $q(z) = -nc_n \frac{z^n}{n}$.

The second row of S is annihilated by $\theta(\theta + b) - (\theta + a)z$, and the residual for truncation at n is given by $q(z) = -nc'_n \frac{z^n}{n}$. Alternatively, if $\rho < 1$ is an upper bound on $\frac{z(k+a)}{(k+1)(k+b)}$ for $k \geq n$,

$$\left| \sum_{k=n}^{\infty} c_k z^k \right| < \frac{|c_n z^n|}{1 - \rho}, \quad \left| \sum_{k=n}^{\infty} c'_k z^k \right| < \frac{|c'_n z^n|}{1 - \rho'}.$$

8.3.2 case $b \in \mathbb{Z}$

We can assume wlog that $1 - b \geq 0$. The general solution takes the form

$$\sum_{k=0}^{\infty} (c_{k,0} + c_{k,1} \log(z)) z^k,$$

and we will identify $c_k = c_{k,0} + c_{k,1} \log(z)$ with the polynomial $c_{k,0}\Lambda + c_{k,1}$ modulo Λ^2 . The two free coefficients are $\chi_0 := c_{0,0}$ and $\chi_1 = c_{1-b,0}$ (or $\chi_1 = c_{0,1}$ if $b = 1$). Let $M_k \in (\mathbb{C}[\Lambda]/\Lambda^2)^{2 \times 1}$ be such that $c_{k,1} + c_{k,0}\Lambda = M_k \begin{pmatrix} \chi_0 \\ \chi_1 \end{pmatrix}$. We have

$$M_k = \begin{cases} (\Lambda, 1), & k = 0 = 1 - b \\ (\Lambda, 0), & k = 0 \neq 1 - b \\ \frac{\Lambda+k+a-1}{\Lambda+k} \frac{M_{k-1}}{\Lambda} + (0, \Lambda), & k = 1 - b \\ \frac{\Lambda+k+a-1}{(\Lambda+k)(\Lambda+k+b-1)} M_{k-1} & \end{cases},$$

with the convention that when a polynomial modulo Λ^2 is divided exactly by Λ , the result is zero-extended to the full precision.

8.4 solution of ${}_1F_1$ equation around a non-singular point x_0

$f(z) = {}_1F_1(a; b|z)$ satisfies

$$f''(z) - (1 - \frac{b}{z})f'(z) - \frac{a}{z}f(z) = 0.$$

We are given $c_0 = f(x_0)$ and $c_1 = f'(x_0)$ as the coefficients $f(x_0 + z) = \sum_{k=0}^{\infty} c_k z^k$ and would like to calculate $f(x_0 + z)$ and $f'(x_0 + z)$ via power series. Set $c'_k := (k+1)c_{k+1}$. With $M_0 = I$ and

$$M_k = \frac{1}{k} \begin{pmatrix} 0 & 1 \\ \frac{k+a-1}{x_0} & 1 - \frac{k+b-1}{x_0} \end{pmatrix} M_{k-1},$$

we have $M_k(\frac{c_0}{c_1}) = (\frac{c_k}{c'_k})$. With $S = \sum_{k=0}^{\infty} M_k z^k$, we have $S(\frac{f(x_0)}{f'(x_0)}) = (\frac{f(z+x_0)}{f'(z+x_0)})$. Fix a truncation point n . The first row of S , i.e. $\sum c_k z^k$, is annihilated by the operator

$$\begin{aligned} & \theta(\theta-1)x_0 + (\theta-1)(\theta+b-2-x_0)z + (2-a-\theta)z^2 \\ &= (\theta-1)\left(\theta + \frac{b-2-x_0}{x_0}z + \sum_{j=2}^{\infty} \left(2-b + \frac{(1-a)x_0}{\theta-1}\right) \frac{z^j}{(-x_0)^j}\right)(z+x_0)^{-1}, \end{aligned}$$

and the residual for truncation at n is given by

$$q(z) = -x_0 n c_n \frac{z^n}{n} - ((b-1+n-x_0)c_n + x_0 c'_n) \frac{z^{n+1}}{n+1}.$$

The second row of S , i.e. $\sum c'_k z^k$, is annihilated by the similar operator

$$\theta(\theta-1)x_0 + (\theta-1)(\theta+b-1-x_0)z + (1-a-\theta)z^2,$$

and the residual for truncation at n is given by

$$q(z) = -x_0 n c'_n \frac{z^n}{n} - (a+n)c_n \frac{z^{n+1}}{n+1}.$$

These are easily combined into a bound on $\sum_{k=n}^{\infty} M_k z^k$.

8.5 continued fraction

The inequalities

$$\int_0^{\infty} e^{-t(1+\frac{b}{x})} t^{a-1} x^{-b} dt < \int_0^{\infty} e^{-t} t^{a-1} (x+t)^{-b} dt < \int_0^{\infty} e^{-t} t^{a-1} x^{-b} dt$$

give, for $a, b, x > 0$,

$$(1 + \frac{b}{x})^{-a} < {}_2F_0(a, b | \frac{-1}{x}) < 1. \quad (8.4)$$

For more accuracy for large x , Taylor's form of the remainder gives

$$\left| (1 + \frac{t}{x})^{-b} - \sum_{k=0}^{n-1} \frac{(b)_k t^k}{k!(-x)^k} \right| \leq \frac{(b)_n t^n}{n! x^n},$$

which, when integrated, shows that we may take $e^? = 1$ in (8.6) when $a, b, x > 0$.

For any integer n , we have

$$\frac{{}_2F_0(b, a+1 | \frac{-1}{x})}{{}_2F_0(b+1, a+1 | \frac{-1}{x})} = 1 + \frac{a+1}{x} + \frac{b+1}{1} + \cdots + \frac{a+n}{x} + \frac{b+n}{\frac{{}_2F_0(b+n, a+n+1 | \frac{-1}{x})}{{}_2F_0(b+n+1, a+n+1 | \frac{-1}{x})}}. \quad (8.5)$$

Since the rhs remainder is easily bound by (8.4), this gives a rigorous algorithm for the quotient. For general a, b, x , (8.6) can be used. The size of this remainder ($\sqrt{n/x}$) can be obtained from the following asymptotic series in $n^{-1/2}$, which follows along the same lines as the derivation of the asymptotic formula for Γ .

$${}_2F_0(a+n, b+n | \frac{-1}{x}) = 2^{-1/2} e^{n-2\sqrt{nx}+\frac{\pi}{2}} \left(\frac{x}{n}\right)^{n+\frac{a}{2}+\frac{b}{2}-\frac{1}{4}} \left(1 + \frac{12(a-b)^2-3-24(a+b-1)x-4x^2}{48\sqrt{nx}} + O\left(\frac{1}{n}\right)\right).$$

8.6 resummation of ${}_2F_0(1, a_1)$

Olver gave an effective absolute error estimate of the form

$$\left| {}_2F_0(a, b|\frac{-1}{x}) - \sum_{k=0}^{n-1} \frac{(a)_k(b)_k}{k!(-x)^k} \right| \leq \frac{|(a)_n(b)_n|}{n!|x|^n} \mathfrak{e}^?, \quad (8.6)$$

but this remainder necessarily has a minimal size, so this formula is only useful up to a certain limited precision depending on the sizes of a and x . On the other hand, any of the formulas (8.2) will require many terms for large $|x|$. Thus, more techniques are in order for large $|x|$, but not so large that (8.6) applies.

Setting $b = 0$ in (8.5) immediately gives a formula for this case. However, this continued fraction cannot converge for $x < 0$ and is ultimately logarithmically convergent where it does converge, so this is also of limited use. (8.2) has the special case

$$\begin{aligned} \mathfrak{e}^{-x} x^{a-1} {}_2F_0(1, 1-a|\frac{-1}{x}) &= \Gamma(a, x) = \Gamma(a) - \frac{x^a}{a} {}_1F_1(a; a+1|-x) \\ &= \Gamma(a) - \frac{x^a}{a} \mathfrak{e}^{-x} {}_1F_1(1; a+1|x) \end{aligned}$$

Analytic continuation can be used for an effective algorithm between this and (8.6), and this is simple enough in this special case to deserve special treatment. If we fix a and put

$$\mathfrak{e}^z \int_0^z \mathfrak{e}^{-t} (1 + \frac{t}{x})^{a-1} dt =: \sum_{k=1}^{\infty} c_k(a, x) z^k \quad |z| < |x|$$

in the $(1, 2)$ entry of a matrix, then the whole matrix can be calculated as

$$S(x, z) := \begin{pmatrix} \mathfrak{e}^z & \mathfrak{e}^{x+z} x^{1-a} (\Gamma(a, x) - \Gamma(a, x+z)) \\ 0 & (1 + \frac{z}{x})^{a-1} \end{pmatrix} = \sum_{k=0}^{\infty} \prod_{j=k}^1 \frac{z}{j} \begin{pmatrix} 1 & 1 \\ 0 & \frac{a-j}{x} \end{pmatrix}. \quad (8.7)$$

Truncation bounds for the diagonal entries are easy (9.1), and the $(1, 2)$ tail is majorized as

$$\begin{aligned} S_{1,2}(x, z) - \sum_{k=1}^{n-1} c_k z^k &\ll \frac{z^n \mathfrak{e}^{\beta_1 z + \beta_2 (-\log(1 - \frac{z}{|x|}) - \frac{z}{|x|})}}{|x| - z} \left((\gamma_0)^+ + (\gamma_1 - \frac{n\beta_1\gamma_0}{n+1})^+ z + (\frac{n\beta_1^2\gamma_0 - n|x|^{-2}\beta_2\gamma_0 - 2(n+1)\beta_1\gamma_1}{2(n+2)})^+ z^2 \right), \\ \beta_1 &= |\frac{1+a+x}{x}|, \quad \beta_2 = \max_{\theta \geq n} |1 + a + \frac{ax}{\theta-1}| \leq \max(|1+a|, |1+a + \frac{ax}{n-1}|) \\ \gamma_0 &= |xc_n|, \quad \gamma_1 = |\frac{(a-n)c_{n-1}}{n(n+1)}| \end{aligned}$$

Set $S = S(x_1, x_2 - x_1)$. The triple of data $(\mathfrak{e}^{-x_2}, x_2^{1-a}, \Gamma(a, x_2))$ can be moved to a triple at x_1 via

$$\begin{aligned} \mathfrak{e}^{-x_1} &= \mathfrak{e}^{-x_2} S_{1,1}, \\ x_1^{1-a} &= x_2^{1-a} S_{2,2}, \\ \Gamma(a, x_1) &= \Gamma(a, x_2) + \frac{\mathfrak{e}^{-x_2} S_{1,2}}{x_1^{1-a}}, \\ {}_2F_0(1, 1-a|\frac{-1}{x_1}) S_{1,1} &= S_{1,2} + {}_2F_0(1, 1-a|\frac{-1}{x_2}) S_{2,2}, \end{aligned}$$

and this constitutes a reverse algorithm. The forward algorithm is similar: Suppose we have the data $(\mathfrak{e}^{x_1}, x_1^{a-1})$ at x_1 and would like to calculate $\Gamma(a, x_1)$. We can push the problem to a new point x_2 via

$$\begin{aligned} \mathfrak{e}^{x_2} &= \mathfrak{e}^{x_1} S_{1,1}, \\ x_2^{a-1} &= x_1^{a-1} S_{2,2}, \\ \Gamma(a, x_1) &= \frac{x_1^{a-1} S_{1,2}}{\mathfrak{e}^{x_2}} + \Gamma(a, x_2). \end{aligned}$$

8.7 resummation of ${}_3F_1(1, a_1, a_2; b_1)$

We would like to calculate this ${}_3F_1(-1/x)$ when x is so large that the convergent series in x require too many terms but not so large that a truncation of the divergent series delivers enough precision.

First, with the goal of effectively calculating the tail of the corresponding Laplace integral, we seek an analogue of the asymptotic for the upper gamma function,

$$\int_z^\infty e^{-t} \left(1 + \frac{t}{x}\right)^{-a_1} dt \sim e^{-z} \left(1 + \frac{z}{x}\right)^{-a_1} \sum_{k=0}^{\infty} \frac{(a_1)_k}{(-z-x)^k}.$$

This is given via various connection formulas by

$$\begin{aligned} \int_z^\infty e^{-t} {}_2F_1\left(\begin{matrix} a_1, a_2 \\ b_1 \end{matrix} \middle| \frac{-t}{x}\right) dt &\sim \frac{\Gamma(b_1)\Gamma(a_2-a_1)}{\Gamma(a_2)\Gamma(b_1-a_1)} e^{-z} \left(1 + \frac{z}{x}\right)^{-a_1} \sum_{k=0}^{\infty} \frac{(a_1)_k}{(-z-x)^k} \sum_{j=0}^k \frac{(-x)^j (b_1-a_2)_j}{j! (1+a_1-a_2)_j} \\ &+ \frac{\Gamma(b_1)\Gamma(a_1-a_2)}{\Gamma(a_1)\Gamma(b_1-a_2)} e^{-z} \left(1 + \frac{z}{x}\right)^{-a_2} \sum_{k=0}^{\infty} \frac{(a_2)_k}{(-z-x)^k} \sum_{j=0}^k \frac{(-x)^j (b_1-a_1)_j}{j! (1+a_2-a_1)_j}. \end{aligned} \quad (8.8)$$

Remark 8.1. *This formula uses the $p = 2$ case of (2.3) and in fact does not generalize to any ${}_pF_{p-1}$, where possibly slower ‘convergence’ is required for a simple formula:*

$$\int_z^\infty e^{-t} {}_pF_{p-1}\left(\mathbf{a}; \mathbf{b} \middle| \frac{-t}{x}\right) dt \sim \sum_{i=1}^p \frac{\Gamma(\mathbf{b})\Gamma(\hat{\mathbf{a}}_i - a_i)}{\Gamma(\mathbf{b} - a_i)\Gamma(\hat{\mathbf{a}}_i)} e^{-z} \left(\frac{z}{x}\right)^{-a_i} \sum_{k=0}^{\infty} \frac{(a_i)_k}{(-z)^k} \sum_{j=0}^k \frac{x^j (1+a_i - \mathbf{b})_j}{j! (1+a_i - \hat{\mathbf{a}}_i)_j}.$$

Next, since we would like to calculate

$${}_3F_1\left(\begin{matrix} 1, a_1, a_2 \\ b_1 \end{matrix} \middle| \frac{-1}{x}\right) = \int_0^\infty e^{-t} {}_2F_1\left(\begin{matrix} a_1, a_2 \\ b_1 \end{matrix} \middle| \frac{-t}{x}\right) dt,$$

we need an analogue of (8.7). Due to the special properties of the ${}_1F_0$ in that case, we were always able to shift the lower limit of integration to 0 in that case. This is no longer possible, so we will consider x fixed in addition to a_1, a_2, b_1 . The analogue of the (2, 2) entry of the matrix is the expansion

$${}_2F_1\left(\begin{matrix} a_1, a_2 \\ b_1 \end{matrix} \middle| \frac{-t}{x}\right) =: \sum_{k=0}^{\infty} d_k(z_1) (t - z_1)^k.$$

The d_k satisfy a recurrence of order 2, and the S function is now a 3x3 sum with 7 entries.

$$S(z, t) := \sum_{k=0}^{\infty} \prod_{j=k}^1 \frac{t}{k} \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -\frac{(k+a_1-1)(k+a_2-1)}{z(z+x)} & \frac{1-b_1-k}{z} + \frac{b_1-a_1-a_2-k}{z+x} \end{pmatrix}, \quad |t| < |z|, |z+x|$$

When $z = 0$, the last row of the displayed matrix should be $0, 0, -\frac{(a_1+k)(a_2+k)}{(b_1+k)x}$ with convergence $|t| < |x|$.

Finally, suppose we have the data $(e^{z_1}, d_0(z_1), d_1(z_1))$ at a point z_1 . At $z_1 = 0$ this data is trivial. The data at a new point z_2 along with the integral between z_1 and z_2 is given by

$$\begin{pmatrix} e^{z_2} & e^{z_2} \int_{z_1}^{z_2} e^{-t} {}_2F_1\left(\frac{-t}{x}\right) dt \\ 0 & d_0(z_2) \\ 0 & d_1(z_2) \end{pmatrix} = S(z_1, z_2 - z_1) \begin{pmatrix} 1 & 0 \\ 0 & d_0(z_1) \\ 0 & d_1(z_1) \end{pmatrix}.$$

We simply iterate this along an appropriate path starting at 0 until (8.8) applies.

8.8 truncation bounds for ${}_3F_1(1, a_1, a_2; b_1)$ resummation

TODO

8.9 bad resummation

The calculation of ${}_2F_0$ follows the process in Section 3. With $\hat{f}(\xi) = \sum_{n=0}^{\infty} \frac{(a)_n(b)_n}{n!^2} \xi^n$, the function $F(x) = \mathbb{E}^{\omega x} \int_0^x \mathbb{E}^{-\omega t} \hat{F}(z\omega t) dt$ is annihilated by $(\theta := x\partial_x)$

$$(\theta - 1)^2 \theta - w(\theta - 1)(z(\theta - 2 + a)(\theta - 2 + b) + \theta - 1)x + w^2 z(\theta - 2 + a)(\theta - 2 + b)x^2$$

and for any x_0 with $x_0(1 - wx_0z) \neq 0$ the function $\tilde{F}(x) = F(x + x_0)$ is annihilated by

$$\begin{aligned} & x_0(1 - wx_0z)\theta(\theta - 1)(\theta - 2) + \\ & (\theta - 1)(\theta - 2)(\theta(1 - 2wx_0z) - wx_0(z(a + b - 5) + 1) + w^2x_0^2z - 2)x + \\ & w(\theta - 2)(-z\theta^2 + (-z(a + b - 6) + 2wx_0z - 1)\theta + wx_0z(a + b - 5) - (a - 3)(b - 3)z + 2)x^2 + \\ & w^2z(\theta - 3 + a)(\theta - 3 + b)x^3 \end{aligned}$$

In general, given $\hat{f}(\xi)$ we would like to compute $\lim_{x \rightarrow \infty} \omega \mathbb{E}^{-\omega x} F(x)$ where

$$\begin{aligned} F(x) &:= \mathbb{E}^{\omega x} \int_0^x \mathbb{E}^{-\omega t} \hat{f}(z(\omega t)^d) dt, \\ F'(x) - wF(x) &= \hat{f}(z(\omega x)^d). \end{aligned}$$

Initial conditions for $\hat{f}(\xi)$ at $\xi = 0$ easily translate to initial condition for $F(x)$ at $x = 0$ when combined with $F(0) = 0$. Next, we integrate these initial conditions from 0 to some x_0 to produce $F(x_0), F'(x_0), \dots, F^{(r+1)}(x_0)$ for some r . Finally, we need to estimate the tail $\int_{x_0}^{\infty} \mathbb{E}^{-\omega t} \delta(t) dt$ where $\delta(x) = F'(x) - wF(x)$. Bounding the coefficients of the differential equation for δ gives a crude bound of the form $|\delta(x)| < \mathbb{E}^{\lambda(x-x_0)} ||\langle \delta(x_0), \delta'(x_0), \dots, \delta^{(r)}(x_0) \rangle||$ for $x > x_0$. If $\lambda < \Re \omega$, then we are done.

9 ${}_0F_0$ and ${}_1F_0$

Majorant method bounds:

$$\begin{aligned} \mathbb{E}^z - \sum_{k=0}^{n-1} \frac{z^k}{k!} &\ll z^n e^z \frac{1}{n!} \\ (1 - z)^{-a} - \sum_{k=0}^{n-1} \frac{(a)_k z^k}{k!} &\ll z^n (1 - z)^{-|a-1|} \frac{|(a)_n|}{n!} \end{aligned} \tag{9.1}$$

Ratio test bounds (assuming $\rho < 1$):

$$\begin{aligned} \left| \sum_{k=n}^{\infty} \frac{z^k}{k!} \right| &\leq \frac{|z|^n}{n!} \frac{1}{1 - \rho}, \quad \rho \geq \max_{k \geq n} \left| \frac{z}{k+1} \right| \\ \left| \sum_{k=n}^{\infty} \frac{(a)_k z^k}{k!} \right| &\leq \frac{|(a)_n z|^n}{n!} \frac{1}{1 - \rho}, \quad \rho \geq \max_{k \geq n} \left| \frac{(a+k)z}{k+1} \right| \end{aligned} \tag{9.2}$$

10 The Γ function

For the definition of the Γ function we will take

$$\begin{aligned}
 \Gamma(z+1) &:= \int_0^\infty t^z e^{-t} dt, \quad \Re z > -1 \\
 &= \lim_{r \rightarrow \infty} \int_0^r t^z (1 - \frac{t}{r})^r dt \\
 &= \lim_{r \rightarrow \infty} r^{z+1} \int_0^1 t^z (1-t)^r dt \\
 &= \lim_{r \rightarrow \infty} r^{z+1} \frac{r!}{(z+1) \cdots (z+r+1)} \\
 &= \prod_{n=1}^\infty \frac{(1 + \frac{1}{n})^z}{1 + \frac{z}{n}},
 \end{aligned}$$

which gives a meromorphic continuation to $z \in \mathbb{C}$ and a clear definition of $\log \Gamma(z+1)$.

Substituting $u = t + s$ and $v = t/(t + s)$ into

$$\Gamma(a)\Gamma(b) = \int_0^\infty \int_0^\infty t^{a-1} s^{b-1} e^{-t-s} dt ds$$

produces

$$\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} = \int_0^1 v^{a-1} (1-v)^{b-1} dv = \int_0^\infty \frac{w^a}{(1+w)^{a+b}} \frac{dw}{w}. \quad (10.1)$$

Let C be the contour that starts below the real axis at $+\infty - \epsilon i$, wraps clockwise around the origin, and returns above the real axis to $+\infty + \epsilon i$.

$$\begin{aligned}
 2\pi i(-1) &= \int_C \frac{(-t)^z dt}{(1+t)t} \quad \text{deform contour hitting residue at } t = -1 \\
 &= \int_\infty^0 \frac{e^{\pi i z} t^z dt}{(1+t)t} + \int_0^\infty \frac{e^{-\pi i z} t^z dt}{(1+t)t} \\
 &= (-e^{\pi i z} + e^{-\pi i z}) \Gamma(z) \Gamma(1-z).
 \end{aligned}$$

The resulting reflection formula $\Gamma(z)\Gamma(1-z) = \pi \csc \pi z$ holds for all z by analytic continuation. This formula also gives a formula for the entire function

$$\frac{1}{\Gamma(z)} = \int_{-\infty}^{(0+)} e^t t^{-z} dt, \quad (10.2)$$

where the contour is the reflection of C about the imaginary axis. The reflection formula also can be derived by integrating the partial fraction decomposition (for $a = \frac{1}{2}$)

$$\sum_{k=1}^\infty \frac{2x \cos(2\pi k a) - 4\pi k \sin(2\pi k a)}{4k^2 \pi^2 + x^2} = \frac{e^{ax}}{e^x - 1} - \frac{1}{x}, \quad 0 < a < 1, \quad (10.3)$$

which can be derived by noting that the difference of both sides is a bounded entire function.

10.1 integral evaluations

We have the following fourier inversion pairs. In the first two, set $y = k + \theta$ where $|\theta| \leq \frac{1}{2}$ and $k \in \mathbb{Z}$.

$$\int_{-\infty}^{\infty} \frac{\Gamma(a+b-1)}{\Gamma(a+x)\Gamma(b-x)} e^{2\pi i x y} dx = (2 \cos \pi \theta)^{a+b-2} e^{-\pi i(a-b)\theta} \begin{cases} 1, & k = 0 \\ 0 & \end{cases}$$

The inversion of this integral follows from (10.1) and the reflection formula. The poisson summation formula applied to this pair is (5.3) for $|z| = 1$. Now, since

$$\begin{aligned} \frac{\Gamma(a-x)\Gamma(b+x)}{2\pi i \Gamma(a+b)} &= \left(\frac{1}{1-e^{2\pi i(x-a)}} - \frac{1}{1-e^{2\pi i(x+b)}} \right) \frac{\Gamma(1-a-b)}{\Gamma(1-a+x)\Gamma(1-b-x)}, \\ \frac{\Gamma(a-b)\Gamma(b+x)}{2\pi i \Gamma(a+x)} &= \frac{1}{e^{\pi i(x+b)} - e^{-\pi i(x+b)}} \frac{\Gamma(a-b)}{\Gamma(a+x)\Gamma(1-b-x)}, \end{aligned}$$

we have two equivalent corollaries (for $\Im a, \Im b \neq 0$):

$$\int_{-\infty}^{\infty} \frac{\Gamma(a-x)\Gamma(b+x)}{2\pi i \Gamma(a+b)} e^{2\pi i x y} dx = \frac{e^{\pi i(a-b)\theta}}{(2 \cos \pi \theta)^{a+b}} \left(e^{2k\pi i a} \begin{cases} +1, \Im a < 0, k \leq 0 \\ -1, \Im a > 0, k > 0 \\ 0 \end{cases} - e^{-2k\pi i b} \begin{cases} +1, \Im b < 0, k > 0 \\ -1, \Im b > 0, k \leq 0 \\ 0 \end{cases} \right)$$

For the second corollary, set $y + \frac{1}{2} = k + \theta$ similarly.

$$\int_{-\infty}^{\infty} \frac{\Gamma(a-b)\Gamma(b+x)}{2\pi i \Gamma(a+x)} e^{2\pi i x y} dx = (2 \cos \pi \theta)^{a-b-1} e^{-\pi i(a+b-1)\theta} e^{(1-2k)\pi i b} \begin{cases} -1, \Im b > 0, k \leq 0 \\ +1, \Im b < 0, k > 0 \\ 0 \end{cases}$$

10.2 Characterization as a log convex function

Lemma 10.1. $f(x) = \log \Gamma(x) = -\log x + \sum_{n=1}^{\infty} x \log(1 + \frac{1}{n}) - \log(1 + \frac{x}{n})$ is the only function $(0, \infty) \rightarrow \mathbb{R}$ satisfying $f(1) = 0$, $f(x+1) = f(x) + \log x$, and $f''(x) > 0$.

Proof. Set $g(x) = f(x) - \log \Gamma(x)$. The conditions become $g(1) = 0$, $g(x+1) = g(x)$, and $g''(x) + \sum_{n=0}^{\infty} (x+n)^{-2} > 0$. Since g'' has period 1 and $\sum_{n=0}^{\infty} (x+n)^{-2} < x^{-1} + x^{-2}$ tends to zero as $x \rightarrow \infty$, we must have $g''(x) \geq 0$. Since g' has period 1, we have $0 = g'(x+1) - g'(x) = \int_x^{x+1} g''(t) dt$, which, when combined with $g''(x) \geq 0$, yields $g''(x) = 0$. The result $g(x) = 0$ follows easily. \square

Corollary 10.2. For any positive integer m ,

$$\Gamma(z) = \Gamma(\frac{z+0}{m}) \Gamma(\frac{z+1}{m}) \cdots \Gamma(\frac{z+m-1}{m}) \cdot m^{z-\frac{1}{2}} \cdot (2\pi)^{\frac{m-1}{2}}.$$

Proof. Given Lemma 10.1, we need to show the right hand side has value 1 at $z = 1$. This constant follows from the reflection formula and the easy identity

$$2^{m-1} \csc(\pi z) = \csc(\pi \frac{z+0}{m}) \csc(\pi \frac{z+1}{m}) \cdots \csc(\pi \frac{z+m-1}{m}).$$

\square

10.3 Standard asymptotic approximation

Lemma 10.3. As $x \rightarrow \infty$,

$$\log \Gamma(x+a) = (x+a-\frac{1}{2}) \log x - x + \frac{1}{2} \log 2\pi + \frac{1-6a(1-a)}{12x} - \frac{a(1-a)(1-2a)}{12x^2} + O_a(\frac{1}{x^3}).$$

Proof.

$$\begin{aligned}
\frac{\Gamma(s+1)}{s^{s+1/2}e^{-s}} &= \frac{1}{s^{s+1/2}e^{-s}} \int_0^\infty x^s e^{-x} dx \\
&= \int_0^\infty e^{s-x+s \log \frac{x}{s}} \frac{dx}{\sqrt{s}} \\
&= \int_{-\sqrt{s}}^\infty e^{-\sqrt{s}x+s \log(1+\frac{x}{\sqrt{s}})} dx \quad x \rightarrow \sqrt{s}x + s \\
&= \int_{-\sqrt{s}}^\infty e^{-\frac{x^2}{2}} \left(1 + \frac{x^3}{3} \frac{1}{s^{1/2}} + \left(\frac{x^6}{18} - \frac{x^4}{4} \right) \frac{1}{s} + \left(\frac{x^9}{162} - \frac{x^7}{12} + \frac{x^5}{5} \right) \frac{1}{s^{3/2}} + \left(\frac{x^{12}}{1944} - \frac{x^{10}}{72} + \frac{47x^8}{480} - \frac{x^6}{6} \right) \frac{1}{s^2} + \dots \right) dx \\
&= \sqrt{2\pi} \left(1 + \frac{1}{12s} + \frac{1}{288s^2} + \dots \right)
\end{aligned}$$

Shifting this by $s \rightarrow x - 1 + a$ and taking the logarithm gives the result. \square

With $\mu_a(z)$ defined by

$$\log \Gamma(z+a) =: (z+a-\frac{1}{2}) \log z - z + \frac{1}{2} \log 2\pi + \mu_a(z).$$

it follows that $\mu_a(+\infty) = 0$ and $\mu_a(z) - \mu_a(z+1) = (\frac{1}{2} + a + z) \log(1 + \frac{1}{z}) - \log(1 + \frac{a}{z}) - 1$, and thus

$$\mu_a(z) = \sum_{n=0}^{\infty} \left(\left(\frac{1}{2} + a + z + n \right) \log \left(1 + \frac{1}{z+n} \right) - \log \left(1 + \frac{a}{z+n} \right) - 1 \right).$$

Another formula for μ and $0 \leq a \leq 1$ can be obtained directly from its definition and integration by parts:

$$\begin{aligned}
\mu_a(z) &= \int_0^1 B_1(\{x-a\}) \log \Gamma'(z+x) dx \quad (\text{proof: exercise}) \\
&= \sum_{n=2}^N \frac{(-1)^n B_n(a)}{n(n-1)z^{n-1}} - \frac{(-1)^N}{N!} \int_0^1 B_N(\{x-a\}) \log \Gamma^{(N)}(z+x) dx.
\end{aligned}$$

10.4 Remainder as a rapidly convergent integral and asymptotic series

Theorem 10.4. For $0 \leq a \leq 1$,

$$\begin{aligned}
\log \Gamma(z+a) &= (z+a-\frac{1}{2}) \log z - z + \frac{1}{2} \log 2\pi - \begin{cases} \log(1 - e^{-2\pi i(z+a)}) & , -\pi < \arg z < -\frac{\pi}{2} \\ \log(1 - e^{+2\pi i(z+a)}) & , +\frac{\pi}{2} \leq \arg z \leq +\pi \end{cases} \\
&\quad + i \int_0^\infty \frac{\log(1 - \frac{it}{z})}{e^{2\pi(t-ia)} - 1} - \frac{\log(1 + \frac{it}{z})}{e^{2\pi(t+ia)} - 1} dt.
\end{aligned}$$

Proof. Assume that $\Re z > 0$. The extra correction term of $\pi^2 \csc^2 \pi(x+a)$ for $\log \Gamma''(z)$ and thus $\mp 2\pi i(1 -$

$e^{\mp 2\pi i(x+a)})^{-1}$ for $\log \Gamma'(z)$ follows from picking up a residue at $t = -z$ when $\Re z < 0$.

$$\begin{aligned}
\log \Gamma''(z+a) &= \sum_{n=0}^{\infty} \frac{1}{(z+a+n)^2} \\
&= \oint \frac{(z+t)^{-2}}{e^{2\pi i(t-a)} - 1} dt \quad \text{around } a, a+1, a+2, \dots \\
&= - \int_{-i\infty}^{+i\infty} \frac{(z+t)^{-2}}{e^{2\pi i(t-a)} - 1} dt \\
&= \int_{-r i}^0 \frac{(z+t)^{-2}}{e^{2\pi i(t-a)} - 1} dt + \int_0^{r i} \left(\frac{1}{e^{2\pi i t} - 1} + 1 \right) (z+t)^{-2} dt \\
&= \frac{1}{z} - i \int_0^{\infty} \frac{(z - it)^{-2}}{e^{2\pi(t-ia)} - 1} - \frac{(z + it)^{-2}}{e^{2\pi(t+ia)} - 1} dt.
\end{aligned}$$

The result follows by integrating this twice and using (10.3) in the form

$$i \int_0^{\infty} \frac{(-it)^n}{e^{2\pi(t-ia)} - 1} - \frac{(it)^n}{e^{2\pi(t+ia)} - 1} dt = \frac{B_{n+1}(a)}{n+1}.$$

□

Applying integration by parts to the integral in the previous proof and expanding it as a partial series in $1/z$ gives (for $\Re z > 0$ and $0 \leq a \leq 1$)

$$\mu_a(z) = \sum_{n=2}^{N+1} \frac{(-1)^n B_n(a)}{n(n-1)z^{n-1}} - \frac{1}{2\pi z^N} \int_0^{\infty} \frac{(it)^N}{z - it} \log(1 - e^{-2\pi(t-ia)}) + \frac{(-it)^N}{z + it} \log(1 - e^{-2\pi(t+ia)}) dt.$$

The first term is an asymptotic series that diverges for all z , since, for example, we have a precise estimate for the coefficients (equivalent to (10.3)):

$$-(2\pi i)^n \frac{B_n(a)}{n!} = \text{Li}_n(e^{2\pi ia}) + (-1)^n \text{Li}_n(e^{-2\pi ia}).$$

10.5 Remainder as a Laplace transform and inverse factorial series

Theorem 10.5. For $\Re z > 0$,

$$\log \Gamma(z+a) = (z+a-\tfrac{1}{2}) \log z + z - \tfrac{1}{2} \log 2\pi + \int_0^{\infty} \left(\frac{e^{-at}t}{1-e^{-t}} - 1 + (a-\tfrac{1}{2})t \right) \frac{e^{-zt}}{t^2} dt.$$

Proof. By expanding $1/(1-e^{-t})$ as a geometric series in e^{-t} , it easily follows that

$$\log \Gamma''(z+a) = \sum_{n=0}^{\infty} \frac{1}{(z+a+n)^2} = \int_0^{\infty} \left(\frac{e^{-at}t}{1-e^{-t}} \right) e^{-zt} dt.$$

Integrating once gives

$$\log \Gamma'(z+a) - \log z = \int_0^{\infty} \left(\frac{e^{-at}t}{1-e^{-t}} - 1 \right) \frac{e^{-zt}}{-t} dt. \quad (10.4)$$

The result follows by integrating again. □

The integrand in the above theorem is a power series at $t = 0$. Note that, with

$$c_k(s, a) = \frac{s^{k+2} - (s-1)^{k+2}}{k+2} + \frac{(s-a)^{k+1} + (s-1)^{k+1}(s-a-\frac{1}{2}) + s^{k+1}(s-a+\frac{1}{2})}{k+1},$$

for an arbitrary shift s , we have

$$\left(\frac{e^{-at}t}{1-e^{-t}} - 1 + (a-\frac{1}{2})t \right) \frac{1}{t^2} = \frac{e^{-st}}{1-e^{-t}} \sum_{k=1}^{\infty} c_k(s, a) \frac{t^k}{k!}.$$

Using the Sirling numbers of the first kind,

$$\frac{t^k}{k!} = \sum_{n=k}^{\infty} \frac{|S_n^{(k)}|}{n!} (1-e^{-t})^n,$$

we derive the representation (usually stated with $s = a = 1$) for $\Re z > 0$,

$$\begin{aligned} \mu_a(z) &= \sum_{n=1}^{\infty} \frac{(n-1)!}{(z+s)_n} \sum_{k=1}^n \frac{|S_n^{(k)}|}{n!} c_k(s, a), \\ &= \sum_{n=1}^{\infty} \frac{(n-1)!}{(z+s)_n} \int_0^1 \frac{(s-x)_n}{n!} (\{a-x\} - \frac{1}{2}) dx, \quad 0 \leq a \leq 1, \end{aligned}$$

where $(x)_n$ denotes the usual Pochhammer symbol and $0 \leq \{x\} < 1$ is the fractional part of the real number x . An alternate derivation of this formula starts with an easy consequence of (10.4):

$$\begin{aligned} \log \Gamma'(z+s) - \log \Gamma'(z+x) &= \int_0^{\infty} \frac{e^{t(s-x)} - 1}{1-e^{-t}} e^{-(z+s)t} dt \\ &= \sum_{n=1}^{\infty} \frac{(s-x)_n}{(z+s)_n n}, \quad \Re z > 0, \end{aligned}$$

where the convergence is uniform on $x \in [0, 1]$. Integrating both sides against $(\{a-x\} - \frac{1}{2}) dx$ gives the same result.

10.6 The Hurwitz Zeta function and antiderivatives of $\log \Gamma$

It is no coincidence that the constant term in the asymptotic expansion of $\log \Gamma$ is $\frac{1}{2} \log 2\pi = -\zeta'(0)$. In this section we will develop formulas relating derivatives and antiderivates of $\log \Gamma$ to the ζ function at integer s .

Define for $0 \leq a \leq 1$ (convergence for $\Re s > -N-1$)

$$\begin{aligned} \zeta(s+1, z+a) &:= \sum_{n=0}^{\infty} \frac{1}{(n+z+a)^{s+1}}, \quad (N = -1) \\ &= \frac{1}{sz^s} - (s+1) \int_0^{\infty} \frac{a - \{a-t\}}{(t+z)^{s+2}} dt, \quad (N = 0) \\ &= \sum_{n=0}^N (-1)^n \frac{(s)_n B_n(a)}{n! s z^{s+n}} - \frac{(s)_{N+1}}{N! s} \int_0^{\infty} \frac{B_N(\{t-a\})}{(t+z)^{s+N+1}} dt, \quad (N \geq 1). \end{aligned} \tag{10.5}$$

This last expansion shows that $\zeta(1 - N, 0 + a) = -\frac{1}{N}B_N(a)$ which holds for all a by analytic continuation. The derivative at $s = -N$ gives (H_k are the harmonic numbers and ζ' denotes the derivative w.r.t s)

$$\zeta'(1 - N, z + a) = \sum_{n=0}^N \binom{N}{n} \frac{B_n(a)}{N} (\log x - \frac{1}{N} + H_N - H_{N-n}) x^{N-n} + \frac{1}{N} \int_0^\infty \frac{B_N(\{t - a\})}{t + z} dt. \quad (10.6)$$

It immediately follows from the definition of ζ that, for any integer $n \geq 2$,

$$\log \Gamma^{(n)}(z) = (-1)^n (n-1)! \zeta(n, z).$$

For $n = 1$, we need to handle the pole of ζ as

$$\begin{aligned} \lim_{s \rightarrow 0} \zeta(1 + s, z) - \frac{1}{s} &= \lim_{s \rightarrow 0} \frac{1}{s z^s} - \frac{1}{s} - (s+1) \int_0^\infty \frac{-\{t\}}{(t+z)^{s+2}} dt \\ &= -\log z + \sum_{n=0}^\infty \int_0^1 \frac{1-t}{(t+n+z)^2} dt \\ &= \lim_{N \rightarrow \infty} -\log z + \sum_{n=0}^{N-1} \frac{1}{n+z} - \log \frac{1+n+z}{n+z} \\ &= \lim_{N \rightarrow \infty} -\log(N+z) + \log \Gamma'(N+z) - \log \Gamma'(z) \\ &= -\log \Gamma'(z) \end{aligned}$$

We can also do something for $n \leq 0$. With the definition $\gamma := -\log \Gamma'(1)$ and from the definition of $\log \Gamma$, we have the Taylor series

$$\log \Gamma(z) = -\log(z) - \gamma z + \sum_{k=2}^\infty (-1)^k \frac{\zeta(k)}{k} z^k.$$

Since we have the clear Taylor series

$$\zeta(s, z) = z^{-s} + \sum_{k=0}^\infty (-1)^k \frac{(s)_k \zeta(s+k)}{k!} z^k,$$

differentiating this at $s = 0$ and comparing the coefficients gives the relation

$$\log \Gamma(z) = \zeta'(0, z) - \zeta'(0).$$

The previously derived asymptotic expansion of $\log \Gamma$ now follows from (10.6). For an antiderivative of order $n \geq 1$, define

$$\log \Gamma^{(-n)}(z) := \int_0^z \log \Gamma^{(1-n)}(t) dt.$$

Since

$$\frac{\partial}{\partial z} \left(\frac{\zeta(s, z)}{s^2} - \frac{\zeta'(s, z)}{s} \right) = \zeta'(1 + s, z),$$

we easily obtain rational polynomials $p_n(z)$ with

$$n! \log \Gamma^{(-n)}(z) = \zeta'(-n, z) - p_n(z) - \sum_{i=0}^n \binom{n}{i} \zeta'(-i) z^{n-i},$$

$$\begin{aligned} p_1(z) &= \frac{1}{2} z^2 - \frac{1}{2} z, \\ p_2(z) &= \frac{1}{2} z^3 - \frac{3}{4} z^2 + \frac{1}{12} z, \\ p_3(z) &= \frac{11}{24} z^4 - \frac{11}{24} z^3 + \frac{5}{24} z^2. \end{aligned}$$

These polynomials in general satisfy $p_0(z) = 0$ and $p_n(z) = \int_0^z n p_{n-1}(t) - \frac{1}{n} B_n(t) dt$.

10.7 The Barnes G function and hyperfactorial

We have three functions that take the value 0 at 1 and satisfy

$$\begin{aligned}\log\Gamma(x+1) &= \log\Gamma(x) + \log(x), \\ \log G(x+1) &= \log G(x) + \log\Gamma(x), \\ \log H(x) &= \log H(x-1) + x \log(x).\end{aligned}$$

The last two are uniquely defined by requiring the third derivative to be positive. This gives

$$\begin{aligned}\log\Gamma(x+1) &= \sum_{n=1}^{\infty} x \log(1 + \frac{1}{n}) - \log(1 + \frac{x}{n}), \\ \log G(x+1) &= -\frac{1}{2}x(x-1) + \sum_{n=1}^{\infty} \frac{1}{2}x(x-1-2n) \log(1 + \frac{1}{n}) + n \log(1 + \frac{x}{n}), \\ \log H(x) &= +\frac{1}{2}x(x-1) + \sum_{n=1}^{\infty} \frac{1}{2}x(x+1+2n) \log(1 + \frac{1}{n}) - (n+x) \log(1 + \frac{x}{n}),\end{aligned}$$

and the obvious relation $x \log\Gamma(x+1) = \log G(x+1) + \log H(x)$. The formulas of the previous sections give the exact formulas

$$\begin{aligned}\log\Gamma(x+1) &= (x + \frac{1}{2}) \log x - x - \zeta'(0) + \int_0^{\infty} \frac{2 \arctan(\frac{t}{x})}{e^{2\pi t} - 1} dt, \\ \log G(x+1) &= (\frac{1}{2}x^2 - \frac{1}{12}) \log x - \frac{3}{4}x^2 - \zeta'(0)x + \zeta'(-1) + \int_0^{\infty} \frac{-t \log(1 + \frac{t^2}{x^2})}{e^{2\pi t} - 1} dt, \\ \log H(x) &= (\frac{1}{2}x^2 + \frac{1}{2}x + \frac{1}{12}) \log x - \frac{1}{4}x^2 + \frac{1}{12} - \zeta'(-1) + \int_0^{\infty} \frac{-2t + 2x \arctan(\frac{t}{x}) + t \log(1 + \frac{t^2}{x^2})}{e^{2\pi t} - 1} dt.\end{aligned}$$

10.8 Formulas for $\gamma = 0.577\dots$

First, a simple derivation of a fact that follows from a limiting case of (4.2) and (8.1) to ${}_2F_2(1, 1; 2, 2|z)$:

Theorem 10.6. For $\Re z > 0$,

$$\int_0^z (1 - e^{-t}) \frac{dt}{t} = \log z + \gamma + \int_z^{\infty} e^{-t} \frac{dt}{t}$$

Proof. Since the derivatives of both sides match, it suffices to establish the constant of integration via asymptotics as $z \rightarrow 0^+$. This follows from

$$\int_z^{\infty} e^{-t} \frac{dt}{t} = \int_z^{\infty} \left(\frac{t}{1 - e^{-t}} - 1 \right) \frac{e^{-t}}{-t} dt + \int_z^{\infty} \frac{e^{-t}}{1 - e^{-t}} dt$$

as the first integral is $-\gamma + O(z)$ by (10.4), and the second is $-\log(z) + O(z)$. □

Theorem 10.7. For $q > 1$,

$$\sum_{n=0}^{\infty} z^n e^{-q^{n-x}} = \sum_{n=0}^{\infty} \frac{(-1)^n q^{-nx}}{(1-zq^n)n!} + \sum_{m=-\infty}^{\infty} e^{(\log z + 2\pi i m)x} \frac{1}{\log q} \Gamma\left(\frac{\log z + 2\pi i m}{\log q}\right).$$

The coefficients incur a pole when $1 = zq^n$ for some $n \geq 0$, in which case the problematic terms must be evaluated separately via limits. For example, when $z = 1$, we have

$$\sum_{n=0}^{\infty} \mathfrak{E}^{-q^{n-x}} = x + \frac{1}{2} - \frac{\gamma}{\log q} + \sum_{n=1}^{\infty} \frac{(-1)^n q^{-nx}}{(1-q^n)n!} + \sum_{m \neq 0} \mathfrak{E}^{2\pi i m x} \frac{1}{\log q} \Gamma\left(\frac{2\pi i m}{\log q}\right).$$

Lemma 10.8. *For $a, z > 0$,*

$$\int_0^{1-\epsilon} \frac{ax^{az}}{1-x^a} \frac{dx}{x} = -\log(a\epsilon) - \log \Gamma'(z) - \gamma + O(\epsilon)$$

Proof. This follows from a limiting case of (2.3), or via the difference of two applications of (10.4). \square

Corollary 10.9. *For integral $0 < b < a$,*

$$\gamma + \log \Gamma'\left(\frac{b}{a}\right) + \log a = \sum_{k=1}^{a-1} \zeta_a^{-bk} \log(1 - \zeta_a^k) = -\frac{\pi}{2} \cot \frac{\pi b}{a} + \sum_{k=1}^{a-1} \cos \frac{2\pi bk}{a} \log\left(2 \sin \frac{\pi k}{a}\right).$$

Corollary 10.10 (Vacca, Ramanujan).

$$\begin{aligned} \gamma &= \int_0^1 \left(\frac{q}{1-x^q} - \frac{1}{1-x} \right) \sum_{n=1}^{\infty} x^{qn} \frac{dx}{x}, \text{ for } q > 1 \\ &= \sum_{n=1}^{\infty} \frac{[\log_q n]}{n} \cdot \begin{cases} q-1 & \text{if } q \mid n \\ -1 & \text{if } q \nmid n \end{cases}, \text{ for integral } q > 1. \end{aligned}$$

11 Tight ${}_2F_1$ bounds everywhere

The analysis is for real parameters $a, b, c \in \mathbb{R}$, but it should be possible to do something for complex parameters too.

With

$$f(w) = (1+w)^{-2a} {}_2F_1 \left(\begin{matrix} a, b \\ c \end{matrix} \middle| \frac{4w}{(1+w)^2} \right) = \sum_{n=0}^{\infty} r_n w^n, \quad |w| < 1 \quad (11.1)$$

we have $r_0 = 1$, $r_1 = \frac{4ab}{c} - 2a$, and $r_{n+1} = \lambda_0(n)r_n + (1 - \lambda_1(n))r_{n-1}$, where

$$\begin{aligned} \lambda_0(n) &= \frac{2(2b-c)(n+a)}{(n+1)(n+c)} \\ \lambda_1(n) &= \frac{2(1-2a+c)(n+a)}{(n+1)(n+c)} \end{aligned}$$

The unit disk $|w| < 1$ is mapped into the whole complex z -plane minus $[1, \infty)$ by $z = \frac{4w}{(1+w)^2}$, hence this provides a method for computing the usual branch of ${}_2F_1$ if we can bound the tails of the sum. Note that $\lambda_0, \lambda_1 \rightarrow 0$, and for the moment entertain the assumption that $|\lambda_0| \leq \lambda_1 \leq 1$ for all n :

$$\begin{aligned} |r_2| &= |\lambda_0 r_1 + (1 - \lambda_1) r_0| \\ &\leq |\lambda_0| |r_1| + (1 - \lambda_1) |r_0| \\ &\leq (|\lambda_0| + 1 - \lambda_1) \max(|r_0|, |r_1|) \\ &\leq \max(|r_0|, |r_1|). \end{aligned}$$

Hence $|r_n| \leq \max(|r_0|, |r_1|)$ for all n by induction. For general real parameters a, b, c the inequality $|\lambda_0(n)| \leq \lambda_1(n)$ is not possible for all n as singularities (either logarithmic or algebraic) of the ${}_2F_1$ at $z = \infty$ and $z = 1$ mean that the r_n can grow like an arbitrarily large power of n .

To remedy this, consider $\tilde{r}_n := r_n n^{-\mu}$ for some arbitrary real μ . The transformed recurrence is $\tilde{r}_n = \tilde{\lambda}_0(n)\tilde{r}_{n-1} + (1 - \tilde{\lambda}_1(n))\tilde{r}_{n-2}$ where

$$\begin{aligned}\tilde{\lambda}_0(n) &= \left(\frac{n}{n+1}\right)^\mu \lambda_0(n) \\ \tilde{\lambda}_1(n) &= 1 - \left(\frac{n-1}{n+1}\right)^\mu (1 - \lambda_1(n))\end{aligned}$$

If $|\tilde{\lambda}_0(n)| \leq \tilde{\lambda}_1(n) \leq 1$ for all $n \geq n_0$, then it follows as above that $r_n \leq \max(|\tilde{r}_{n_0}|, |\tilde{r}_{n_0-1}|)n^\mu$ for all $n > n_0$. There are two ways to turn this into an algorithm for bounding the tails. Either choose an n_0 and compute a μ (not recommended), or since

$$\begin{aligned}\tilde{\lambda}_0(n) &= 2(2b - c)n^{-1} + O(n^{-2}) \\ \tilde{\lambda}_1(n) &= 2(1 - 2a + c + \mu)n^{-1} + O(n^{-2})\end{aligned}$$

we can choose any $\mu > -1 + 2a - c + |2b - c|$ and compute an n_0 . This is an optimal bound on μ .

12 Tight ${}_3F_2$ bounds near 1

Series expansions of solutions around $z = 1$ can be constructed as

$$\sum_{n=0}^{\infty} r_n (1 - z)^{n+\lambda}$$

where $\lambda = 0$ or $\lambda = b_1 + b_2 - a_1 - a_2 - a_3$ and $r_{n+2} + \kappa_1(n)r_{n+1} + \kappa_0(n)r_n = 0$ where

$$\begin{aligned}\kappa_0(n) &= \frac{(a_1 + \lambda + n)(a_2 + \lambda + n)(a_3 + \lambda + n)}{(\lambda + n + 1)(\lambda + n + 2)(a_1 + a_2 + a_3 - b_1 - b_2 + \lambda + n + 2)} \\ &= 1 + (b_1 + b_2 - 5)n^{-1} + O(n^{-2}) \\ \kappa_1(n) &= -2 - (b_1 + b_2 - 5)n^{-1} + O(n^{-2})\end{aligned}$$

For $\lambda = b_1 + b_2 - a_1 - a_2 - a_3$ the r_n are determined once r_0 is fixed, while for $\lambda = 0$, the r_n depend freely on r_0 and r_1 . This gives 3 solutions.

By the substitution $r_n = \tilde{r}_n n^\mu$ where $\mu = -2 + \max(b_1, b_2)$, this equation can be brought to the form

$$\tilde{r}_{n+2} + \left(-2 + \frac{d_1}{n} + \frac{d_2}{n^2} + O\left(\frac{1}{n^3}\right)\right)\tilde{r}_{n+1} + \left(1 - \frac{d_1}{n} - \frac{d_2}{n^2} + O\left(\frac{1}{n^3}\right)\right)\tilde{r}_n = 0$$

where crutially $d_1 = 1 + |b_1 - b_2|$ is positive. This equation can be rewritten as

$$\tilde{r}_{n+2} - \tilde{r}_{n+1} = \left(1 - \frac{d_1}{n} - \frac{d_2}{n^2}\right)(\tilde{r}_{n+1} - \tilde{r}_n) + O\left(\frac{\max(|\tilde{r}_{n+1}|, |\tilde{r}_n|)}{n^3}\right)$$

All constants hidden by the O notation are effective and depend only on the parameters b_i, a_i . We would like to show that $\tilde{r}_n = O(n^\epsilon)$ for every $\epsilon > 0$.

13 implementation [section is boring, messy, incomplete]

13.1 transformations of differential equations

We use $\theta := \theta_x := x\partial_x$ and note the non-commutative operator relation $\theta x^n = x^n(\theta + n)$. We maintain differential equation either in x and θ (with θ either on the left or right) or in x and ∂ (with ∂ on the right). The relation between powers of θ and powers of ∂ is given by

$$\begin{aligned}\theta^n x^m &= \sum_{i=0}^n \mathcal{S}_n^{(i)}(m) x^{m+i} \partial^i, \\ x^{m+n} \partial^n &= x^m \theta(\theta - 1) \cdots (\theta - (n - 1)) =: x^m \theta^{(n)} \\ &= (\theta - m)(\theta - (m + 1)) \cdots (\theta - (m + n - 1)) x^m\end{aligned}$$

where $v^{(n)}$ denotes the falling factorial and the specialization $m = 0$ produces coefficients $\mathcal{S}_n^{(i)}(0)$ which are the Stirling numbers of the second kind.

13.1.1 rescale

For $T(f(x)) = f(s\xi)$, we have

$$\begin{aligned}T\partial_x &= 1/s\partial_\xi T, \\ T\theta_x &= \theta_\xi T, \\ Tx &= s\xi T.\end{aligned}$$

13.1.2 inflate

For $T(f(x)) = f(\xi^s)$, it is best to work with the $x - \theta_x$ form.

$$\begin{aligned}T\partial_x &= \xi^{1-s}/s\partial_\xi T, \\ T\theta_x &= 1/s\theta_\xi T, \\ Tx &= \xi^s T.\end{aligned}$$

13.1.3 Borel

For $T = \mathcal{B}_{1/d}$, it is best to work with the $x - \theta_x$ form.

$$\begin{aligned}T\theta_x &= \theta_\xi T, \\ Tx^{-1/d} &= \xi^{-1/d} d\theta_\xi T, \\ Tx^{-n/d} &= \xi^{-n/d} (d\theta_\xi)^{(n)} T.\end{aligned}$$

Lemma 13.1. *If, for some polynomials p_i , $f(z)$ satisfies $\sum_{i=0}^n p_i(\theta_z) z^i f(z) = 0$, then $\hat{f}(\xi) = \mathcal{B}_{1/d}(f(z))$ satisfies $\sum_{i=0}^n (d(\theta_\xi - i))^{(d(n-i))} p_i(\theta_\xi) \xi^i \hat{f}(\xi) = 0$.*

13.1.4 shift

For $T(f(x)) = f(\xi + s)$, it is best to work with the $x - \partial_x$ form.

$$\begin{aligned}T\partial_x &= \partial_\xi T, \\ T\theta_x &= (1 + s/\xi) \theta_\xi T, \\ Tx &= (\xi + s) T.\end{aligned}$$

13.1.5 Laplace

For $(Tf)(x) = e^{wx} \int_0^x e^{-wt} f(t) dt$, it is also best to work with the $x - \partial_x$ form where we can use

$$(\partial_x - w)(Tf)(x) = f(x).$$

13.2 majorant method

This is a terse summary of “Truncation Bounds for Differentially Finite Series” by Messarobba. We would like to study the various functions

$$F(z), \quad F\left(\frac{1}{z}\right), \quad F(1-z), \quad (1+z)^{-2a_p} F\left(\frac{4z}{(1+z)^2}\right), \quad \dots$$

as convergent power series for $|z| < 1$ as this allows for the computation of F everywhere. In order to evaluate these power series, we need bounds on the coefficients, and tight bounds are already difficult to prove for ${}_2F_1$ and ${}_3F_2$. If we are not near the radius of convergence of these series, an overestimation of the coefficients is acceptable if it allows us to actually get proven bounds.

Each of these functions $f(z)$ satisfies a homogeneous linear differential equation $P(f(z)) = 0$ which will we write in terms of $\theta = z\partial_z$. Since $z\theta = (\theta - 1)z$, we can write the operator P with θ on the left. When θ is on the left and z is on the right, it is easy to transform the differential equation to a recursion on the coefficients. For example, for $F(z) = {}_2F_1(a_1, a_2; b_1|z) = \sum_{n=0}^{\infty} u_n z^n$, we have

$$P = (\theta + b_1 - 1)(\theta) - (\theta + a_1 - 1)(\theta + a_2 - 1)z \Leftrightarrow \frac{u_n}{u_{n-1}} = \frac{(n + a_1 - 1)(n + a_2 - 1)}{(n + b_1 - 1)(n)}$$

13.2.1 coefficient recursions

Write the differential operator as $P(z, \theta) = \theta^r p_r(z) + \dots + \theta p_1(z) + p_0(z) = P_s(\theta)z^s + \dots + P_1(\theta)z + P_0(\theta) \in \mathbb{F}[z, \theta]$ with θ on the left and assume that $p_r(0) \neq 0$. Define the operator $L(z, \theta) = P(z, \theta)p_r(z)^{-1} = \sum_{j=0}^{\infty} Q_j(\theta)z^j$ and note that $\deg(Q_0(\theta)) = r$ and $\deg(Q_j(\theta)) < r$ for $j > 0$. Let $\lambda \in \overline{\mathbb{F}}$ denote a fixed root of Q_0 such that none of $\lambda - 1, \lambda - 2, \dots$ is a root of Q_0 . Let $\mu(\nu)$ denote the multiplicity of ν as a root of Q_0 (or as a root of P_0). For a double sequence $\{u_{\lambda+n,k}\}_{n,k \geq 0}$, let

$$u(z) = \sum_{\substack{n=0 \\ \nu=\lambda+n}}^{\infty} \sum_{k=0}^{\infty} u_{\nu,k} z^{\nu} \frac{\log^k z}{k!},$$

be a solution to $P(z, \theta)(u(z)) = 0$. This is actually a polynomial in $\log z$, so let $\tau(n)$ be a nondecreasing integer-valued function of n satisfying $u_{\lambda+n,k} = 0$ for $k \geq \tau(n)$. We will see shortly that we can take $\tau(0) \leq \mu(\lambda + 0)$ and $\tau(n) \leq \tau(n-1) + \mu(\lambda + n)$. In terms of the operator S_k , which shifts a sequence $\{a_k\}_{k \geq 0}$ to $\{a_{k+1}\}_{k \geq 0}$, the differential equation says that

$$P_0(\nu + S_k)u_{\nu} = - \sum_{j=1}^s P_j(\nu + S_k)u_{\nu-j}$$

Since $P_0(\nu + S_k) = S_k^{\mu(\nu)}(c_0 + c_1 S_k + \dots)$, this equation allows us to determine all $u_{\lambda+n,k}$ with $k \geq \mu(\lambda + n)$ once the initial values $E_{\lambda} = \{u_{\lambda+n,k} \mid 0 \leq k < \mu(\lambda + n)\}$ are determined. Considering all possible λ gives r linearly independent solutions to $P = 0$.

13.2.2 tail bounds

Let $K < \tau(\infty)$ denote the highest power of $\log z$ occuring in $u(z)$, and consider the truncation

$$\tilde{u}(z) = \sum_{n=0}^{N-1} \sum_{k=0}^K u_{\lambda+n,k} z^{\lambda+n} \frac{\log^k z}{k!},$$

and the normalized residual $q(z)$ defined by $P(z, \theta)(\tilde{u}(z)) = Q_0(\theta)q(z)$. This has the form

$$q(z) = \sum_{j=0}^{s-1} \sum_{k=0}^K q_{\lambda+N+j,k} z^{\lambda+N+j} \frac{\log^k z}{k!}$$

where the $q_{\lambda+N}, \dots, q_{\lambda+N+s-1}$ can be computed from $P(z, \theta)$ and $u_{\lambda+N-1}, \dots, u_{\lambda+N-s}$.

Consider $y(z) = p_r(z)(\tilde{u}(z) - u(z))$ as a solution of $L(z, \theta)(y(z)) = Q_0(\theta)(q(z))$. Suppose that for some $n_0 > 0$ we have constructed power series $\hat{a}(z) = \sum_{j>0} \hat{a}_j z^j$, $\hat{q}(z) = \sum_{n>0} \hat{q}_n z^n$, and $\hat{y}(z) = \sum_{n \geq 0} \hat{y}_n z^n$ with nonnegative coefficients satisfying

1. For all $j > 0$ and $n \geq n_0$,

$$n \sum_{t=0}^{\tau(n)-1} \left| [X^t] \frac{Q_j(\lambda + n + X)}{X^{-\mu(\lambda+n)} Q_0(\lambda + n + X)} \right| \leq \hat{a}_j.$$

2. For all $n \geq n_0$ and $k \geq 0$, $|q_{\lambda+n,k}| \leq \hat{q}_n$.

3. $|y_{\lambda+n,k}| \leq \hat{y}_n$ for all $n < n_0$ and $k \geq 0$.

4. $|y_{\lambda+n,k}| \leq \hat{y}_n$ for all $n \geq n_0$ and $k < \mu(\lambda + n)$.

5. $\hat{y}(z)$ satisfies

$$z\hat{y}'(z) = \hat{a}(z)\hat{y}(z) + \hat{q}(z).$$

If all of these are true, we have $|z^{-\lambda}y(z)| \leq \hat{y}(z)$. The reason for dividing the differential equation by $p_r(z)$ on the right is that $\deg Q_j < \deg Q_0$, so we can expect finite values for the \hat{a}_j .

Now, we have

$$\sum_{j=1}^{\infty} Q_j(\theta) z^j = \frac{P(z, \theta)}{p_r(z)} - Q_0(\theta) = \frac{P(z, \theta)}{p_r(z)} - \frac{P(0, \theta)}{p_r(0)}.$$

For all differential equations arising from hypergeometric functions considered here, $\sum_{j=1}^{\infty} Q_j(\theta) z^j$ will be a finite linear combination of functions of the form $(i, k \geq 0)$

$$\begin{aligned} & z^i, \quad z \partial_z \frac{z^i}{(1-z)^k}, \quad z \partial_z \log \left(\frac{1}{1-z} \right), \\ & z \partial_z \frac{z^i}{(1-z^2)^k}, \quad z \partial_z \log \left(\frac{1}{1-z^2} \right), \quad z \partial_z \log \left(\frac{1+z}{1-z} \right), \end{aligned}$$

all with nonnegative coefficients as power series in z .

Remark 13.2. *This is not accurate for equations arising from Borel resummation, where the list needs to be augmented by*

$$\begin{aligned} z\partial_z \log\left(\frac{1}{1-\alpha z}\right) &\ll z\partial_z \log\left(\frac{1}{1-|\alpha|z}\right) \\ z\partial_z \frac{z^i}{(1-\alpha z)^k} &\ll z\partial_z \frac{z^i}{(1-|\alpha|z)^k} \end{aligned}$$

The coefficients of the linear combination, say $f_j(\theta)$, will be polynomials in θ . Bounding the combinations

$$n \sum_{t=0}^{\tau(n)-1} \left| [X^t] \frac{f_j(\lambda + n + X)}{X^{-\mu(\lambda+n)} Q_0(\lambda + n + X)} \right|$$

for each j and for all $n \geq n_0$ will give a valid $\hat{a}(z)$ and a nice formula for $\hat{h}(z) = \exp \int_0^z \hat{a}(z)/z dz$. It now suffices to choose a $\hat{q}(z)$ so that

$$\hat{y}(z) = \hat{h}(z) \int_0^z \frac{\hat{q}(z)/z}{\hat{h}(z)} dz$$

satisfies conditions 2 and 4. If the normalized residue looks like

$$z^N(q_0 + q_1 z + \cdots),$$

define

$$\begin{aligned} \hat{f}(z) &= \hat{f}_0 + \cdots + \hat{f}_s z^s, \quad \hat{f}_i \geq (N+i)|q_i|, \\ g(z) &= g_0 + \cdots + g_s z^s = z^{-N} \int_0^z z^{N-1} \frac{\hat{f}(z)}{\hat{h}(z)} dz + O(z^{s+1}), \\ \hat{g}(z) &= (g_0)^+ + \cdots + (g_s)^+ z^s. \end{aligned}$$

Then, the remainder is majorized by $z^N \hat{g}(z) \hat{h}(z) / \hat{p}(z)$

13.3 series evaluation

For large enough τ , the solution takes the form

$$f(z) = \sum_{i=0}^{\infty} \sum_{j=0}^{\tau-1} u_{i,j} z^{\lambda+i} \frac{\log(z)^j}{j!},$$

and the coefficients $u_{i,j}$ satisfy $u_{i,j} = 0$ for $j \geq \tau$. Therefore, write $u_i = \sum_{j=0}^{\tau-1} u_{i,j} \Lambda^{\tau-1-j}$ where *everything is modulo Λ^τ* . Eventually the coefficients u_i satisfy a relation of the form

$$u_n = a_1 u_{n-1} + \cdots + a_s u_{n-s}, \quad a_i \in \mathbb{F}(n)[\Lambda] \quad (13.1)$$

Let $M_n \in \mathbb{F}(n)[\Lambda]^{s \times s}$ be the companion matrix (with the a_i on the first row) such that

$$\begin{pmatrix} u_n \\ \vdots \\ u_{n-(s-1)} \end{pmatrix} = M_n \begin{pmatrix} u_{n-1} \\ \vdots \\ u_{n-s} \end{pmatrix}$$

Set $f_{[N_0, N_1]}(z) = \sum_{i=N_0}^{N_1-1} z^{\lambda+i} u_i(\log(z))$ where $u_i(\log(z))$ denotes $u_i \in \mathbb{F}[\Lambda]$ with $\Lambda^{\tau-1-j}$ replaced by $\log(z)^j/j!$. For the derivative $f^{(d)}(z)$ of order d we have

$$\begin{pmatrix} f_{[N_0, N_1]}^{(d)}(z) \\ ? \\ \vdots \end{pmatrix} = \sum_{i=N_0}^{N_1-1} z^{\lambda+i-d} (\Lambda + \lambda + i)^{(d)} \prod_{i \geq \ell \geq N_0} M_\ell \begin{pmatrix} u_{N_0-1} \\ \vdots \\ u_{N_0-s} \end{pmatrix} (\log(z))$$

where $x^{(d)} := x(x-1)\cdots(x-(d-1))$ on the right hand side denotes the falling factorial. Therefore, to evaluate several derivatives of f , it suffices to take the first entry of the right hand side for several values of d , where the products $\prod_{N_0 \leq \ell < i} M_\ell$ can be reused. Furthermore, the final product $\prod_{N_0 \leq \ell < N_1} M(\ell)$, when multiplied by the initial values $u_{N_0-1}, \dots, u_{N_0-s}$, gives the final $u_{N_1-1}, \dots, u_{N_1-s}$, which are needed for the estimation of the tail $\sum_{i=N_1}^{\infty} z^i u_i(\log(z))$.

To avoid either a catastrophic linear loss of precision when the a_i are approximate quantities or a slow algorithm when the a_i are “small” exact quantities, the above sum should be evaluated via binary splitting: that is, for example

$$\begin{aligned} \sum_{i=0}^7 z^i \prod_{i \geq \ell \geq 0} M_\ell &= (M_0 + zM_1M_0 + z^2(M_2 + zM_3M_2)M_1M_0) \\ &\quad + z^4(M_4 + zM_5M_4 + z^2(M_6 + zM_7M_6)M_5M_4)M_3M_2M_1M_0. \end{aligned}$$

13.4 putting everything together

This section discusses the reliable evaluation of the solution and its derivatives $f(z), f'(z), \dots, f^{(\delta-1)}(z)$, which can be written as

$$f^{(d)}(z) = f_{[0, N_0]}^{(d)}(z) + f_{[N_0, N]}^{(d)}(z) + f_{[N, \infty)}^{(d)}(z)$$

where

$$f_{[N_0, N_1]}(z) = \sum_{N_0 \leq i < N_1, j} u_{i,j} z^{\lambda+i} \frac{\log(z)^j}{j!}$$

The quantities $z^{\lambda+i} \log(z)^j/j!$ for integers i and j need to be evaluated reliably. This is a problem when z is zero or a ball containing zero.

The first block $f_{[0, N_0]}^{(d)}(z)$ includes those “problematic” terms $u_{i,j} z^{\lambda+i} \log(z)^j/j!$ where $\lambda + i$ is a root of $Q_0(\theta)$. These terms are problematic because the denominators of (13.1) could vanish, thus they should be dealt with separately. For each of these terms we just evaluate $z^{\lambda+i} \log(z)^j/j!$ directly and take care when z contains zero, where the sign of $\Re(\lambda + i)$ is relevant.

The next block also requires care with respect to the evaluation of $\log(z)$. What we actually get out of the previous section is a reliable evaluation of

$$z^{d-N_0-\lambda} f_{[N_0, N]}^{(d)}(z) = \sum_{j=0}^{\tau-1} e_j \Lambda^{\tau-1-j} \in \mathbb{C}[\Lambda],$$

that is, we still have to evaluate $\sum_{j=0}^{\tau-1} e_j z^{\lambda+N_0-d} \log(z)^j/j!$ as reliably as possible. For this, it is helpful if $\Re(\lambda + N_0 - d) > 0$ which is why it is a good ideal to at least choose an $N_0 \geq \delta$.

For the final block, the majorant method produces a power series $\hat{B}(z) = \sum_{i=0}^{\infty} b_i z^i \in \mathbb{R}_{\geq 0}[z]$ with $z^N \hat{B}(z)$ majorizing the tail $\sum_{i=N}^{\infty} u_{i,j} z^i$ for all $j < \tau$. Thus to bound $|f(z)| + |f'(z)|\epsilon + \dots + |f^{(\delta-1)}(z)|/(\delta-1)!\epsilon^{\delta-1}$, we need to calculate, while working in ϵ modulo ϵ^δ , a majorant (in ϵ) of $(z + \epsilon)^{\lambda+N} \log(z + \epsilon)^j/j!$ for each $j < \tau$,

add these up, and multiply the sum by $B(z + \epsilon)$. Since the derivatives of $z^\delta \log(z)^j$ up to and including order $\delta - 1$ are continuous at $z = 0$, it suffices to steal z^δ from the $z^{\lambda+N}$. If the deficit $z^{\lambda+N-\delta}$ is not continuous at $z = 0$, the situation is hopeless anyways. For fixed δ we have

$$(z + \epsilon)^\delta \log(z + \epsilon)^j = \sum_{k=0}^{\delta-1} c_{j,k}(\log(z)) z^{\delta-k} \epsilon^k + O(\epsilon^\delta)$$

for certain polynomials $c_{j,k}$ of degree j satisfying $c_{j+1,k} = \log(z)c_{j,k} + \sum_{\ell=1}^k (-1)^{\ell-1} c_{k-\ell}/\ell$.
